Symour's Monthly Meteorological Magazine, August.—British local meteorological publications. This is a useful list, referring mostly to the year 1897, of books and pamphlets containing observations made in the British Islands, and arranged according to counties. Leaving out of consideration official publications such as issued by the Meteorological Office on the part of the Government, or those emanating from private institutions, such as the Royal and Scottish Meteorological Societies, one is struck by the numerous independent stations at which attention is paid to the subject in question, some of which might advantageously connect themselves with the Central Office. In the majority of counties the Medical Officers of Health publish valuable observations in their reports, in addition to these, we can only refer to a very few of the private organisations which publish observations for a number of stations. For Surrey and Kent, the Croydon Natural History Club prints daily rainfall values for about seventy stations. Similarly, in Herefordshire, the Natural History Society publishes rainfall values for several stations, and there is also a county organisation in Northampton. In Norfolk, the Rev Canon De Port has published monthly rainfall values at about forty stations for more than a quarter of a century. The rainfall of Dorset has been discussed with great care by Mr H. Storks Eaton, and tabulated results for many stations are published in Gloucester, Hereford, Lincolnshire (fifty stations), Nottingham, Lancashire, and many others.—Results of meteorological observations at Camden square (N.W. London) for July for forty years, 1858-97. The highest maximum temperature for the period was 94° 6 (July 15, 1881), and the mean of all the highest readings was 85° 2; this year the maximum for the month was 82° 9. The average rainfall is 2.39 inches, the fall for July this year only amounted to 1.09 inches.

Annalen der Physik und Chemie, No. 7.—Questions concerning the motion of translation of the luminiferous ether, by W. Wien. If the ether is immovable, a thin plate possessing different radiating powers for heat rays on its two faces, could put itself into motion by virtue of the difference of pressure on the two faces. It is possible that the ether is carried along by the earth, but not by bodies of small mass.—The behaviour of cathode rays parallel to the electric force, by P. Lenard. When a beam of cathode rays is sent through a perforated condenser, in the direction of the lines of electric force, its velocity is retarded, and it is more subject to deflection by a magnetic or electrostatic field.—The dark cathode space, by A. Wenneil. The resistance of the dark space to electric discharge is considerable. When the discharge proceeds through the dark space only, it has a disruptive character, as if the dark space were a dielectric like paraffin oil. This can be shown by introducing the anode into the dark space itself. Waves proceed from the discharge tube, and may be placed in evidence by means of a coherer.—Microscopic observations of coherers, by L. Arons. The author's coherers were made by cutting a fine line across a thin strip of tinfoil stuck on glass, laying a little metallic powder across it, adding a drop of Canada balsam, and covering with a cover glass. The newly prepared coherers had an infinite resistance. The impact of electric waves produced full contact, accompanied by a commotion of the particles and a play of sparks, as seen under the microscope.—Electrolytic solution of platinum and gold, by M. Margules. Platinum may be dissolved in acids or caustic alkalis by sending the secondary current from an induction coil through an electrolytic cell with platinum electrodes. Gold is similarly dissolved, but its solutions are very sensitive to light.—Theoretical derivation of the constant of Dulong and Petit's law, by H. Staigmüller. The derivation is based upon the assumption that the temperature of a solid is determined by the mean kinetic energy of the atom oscillating about a position of equilibrium.

Memoirs of the St. Petersburg Society of Naturalists Zoology and Physiology, vol. xxviii. No. 2.—Researches into the history of development of Cephalopoda; and biological observations on Lamellibranchiata, the formation of pigment in *Mytilus*, and the autonomy of the syptoms in *Solen* and *Solenaster*, by V. A. Faussek. A detailed work, 270 pages, with 8 plates and figures in the text.—Vol. xxviii. No. 3. The changes of irritability of a muscle under the influence of a direct current, by Prof. V. A. Kovalevsky (published in *Comptes rendus*).—Ophthalmological researches in the Government of Pskov, by K. M. Deryughin. Based upon the author's four

years' researches and collections, as also upon the collections of Profs. Zarudnyi and Karéeff. The author distinguishes between the fauna of two great lakes, the fields (very poor), and the forest region. Full lists of birds in these three regions are given.—On the wandering cells of the bowels of the Seachurch, by Prof. C. Saint Hilaire. A detailed work of 170 pages, with 136 figures. Its important conclusions, especially as regards the clear distinction between the granular cells and the phagocyte cells, and the functions of the former, are fully summed up by the author, in German.

Bulletin de l'Académie des Sciences de St. Pétersbourg, September 1897, tome vi. No. 2.—On Auerbachite and the rock which contains it, by P. Ereméeff (Russian). A closer study of this mineral shows that it cannot be considered as a separate species, or even as a variety or a pseudomorph of well-known minerals.—The Gastropods of the Baltic Lower Silurian, by Ernst Koken (German). A detailed monograph, with forty-three woodcuts; it is, however, only a preliminary report on the author's larger work upon which he was engaged for the last ten years. Over 200 species are mentioned, and more than one-half of them are new.

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, September 5.—M. Wolf in the chair.—Observations on the planet Witt (1898, August 14), made at the Observatory of Algiers, by M. F. Sy. Positions of the planet are given for August 16, 17 and 18.—Observations on the same planet made at the Observatory of Beaumont, by M. Gruy. Measurements of the planet's position on the nights of August 17 to 20, and 25 to 27 are given. The planet is about the eleventh magnitude.—On a silicide of tungsten, by M. E. Vigouroux. A mixture of silicon and oxide of tungsten on heating in the electric furnace gives a crystalline mass containing the new silicide, metallic tungsten, silica, and carbon silicide. The tungsten is first removed by making the ingot the positive pole in a 10 per cent. solution of hydrochloric acid, and passing an electric current. The crystalline residue, after treating successively with aqua regia, ammonia, hydrofluoric acid, and methylated iodide, is the pure silicide W_2Si . The crystals are steel grey in colour, very heavy (density 19), and are attacked by chlorine at a dull red heat.—On *Artemelema*, a genus found in the Paraná termites, representing a new type of mammifer, by M. Ameghino. An examination of the skull of a small tertiary mammal, found by M. Scalabrini in the neighbourhood of Paraná, leads to the conclusion that the fossil does not correspond with that of any known living or fossil mammal. The shape of the incisors, the separation of the mandibular branches, the widened form of the cranium, the arrangement of the orbits suggest a form allied to the Lemniscus; but the oblique curve of the intermaxillaries, as well as the general *facies*, appears to show affinities with the bats. Other features, amongst which may be mentioned the complete obliteration of the nasal opening, have not been met with either in mammals or reptiles.—On the anatomical structure of the stem of the beet-root, by M. Georges Fron. The thickening of the stem is produced, not by the formation of generating layers as in the root, but by the displacement of one single generating layer towards the exterior. This layer, at first of normal origin, becomes partly normal and partly pericycle, and finally completely pericycle.—On the toxicity of copper salts with regard to the higher vegetables, by M. Henri Coupin. Experiments were made with solutions of various salts of copper (bromide, chloride, sulphate, acetate, and nitrate) upon young wheat plants. All the salts studied had very nearly the same toxic power: a solution of copper sulphate containing only 0.055 per cent. of the salt is sufficient to prevent the germination of wheat, and hence the proposed application of this salt to kill noxious weeds is of very doubtful advantage.—The tufa of the Gaubert (Dordogne), by M. Emile Rivière.

NEW SOUTH WALES

Linnean Society, July 28.—Mr. Henry Deane, Vice-President, in the chair.—Revision of the Australian *Cryptorhynchidae* belonging to the subfamily *Cryptorhynchidae*. Part II. By Arthur M. Lea. Four new genera are proposed, of which three are founded on species referred by Mr. Pascoe to *Periphrus*; and four genera allied to *Periphrus* are re-described. These comprehend a total of thirty-one species which receive attention, fifteen of them being described as new.—Decomp-

tions of new Mollusca from Victoria. By J. Brazier. Four species referable to the genera *Conus*, *Columbella* (*Mitrella*), *Lucina* (*Costellaria*), and *Tellina* (*Strigella*) are described as new. *Hah*.—San Remo.—Notes on some Port Jackson plants. By J. H. Maiden and J. H. Camfield. (a) A well-marked variety (*serotina*) of *Sprongium inornatum* L. is described. (b) The authors propose to restore *Banksia pulchella* B. R. (which had been reduced by Bentham to a variety of *B. integrifolia*) to the rank of a species.—Revision of the genus *Paropsis*. Part III. By Rev. T. Blackburn. In this paper the author takes in hand the species forming Group vi. of the classification propounded in an earlier paper; and three subgroups are dealt with. In addition to critical remarks and tabulations, descriptions of thirteen new species are given.

BOOKS, PAMPHLETS, AND SERIALS RECEIVED.

THE FAUNA AND FLORA OF THE PAMIR

Report on the Natural History Results of the Pamir Boundary Commission By A. W. Alcock, M.B., Surgeon Naturalist to the Commission With a List of the Plants, by J. F. Duthie, B.A., F.L.S., and a Notice of the Rock-specimens, by T. H. Holland, A.R.C.S., F.G.S. (Calcutta, 1898.)

FOR this useful addition to our knowledge of the Pamir plateau we are indebted to the enlightened policy of the Government of India, who, in attaching Mr Alcock as naturalist to the Commission despatched in 1895 to demarcate the boundary between Afghan and Russian territory, followed the course adopted on several previous occasions, as when the late Dr Stoliczka was sent as naturalist with the Yarkand mission in 1873-74, and when Dr J. Anderson was added to the two expeditions to Yunnan in 1868 and 1875. The Indian Government have added to the value of the observations made by publishing the results, which comprise a few general remarks on the fauna, flora and geology, and a descriptive list of the specimens obtained.

The Commission left the valley of Kashmir on June 21, and returned to it on October 12, so that the journey occupied less than four months, whilst the time actually spent in the Pamir itself extended only from July 20 to September 16. This, however, is probably the best time in the whole year for zoological and botanical collecting at so high an elevation, and is certainly much better than April and May, when Stoliczka's collections were made in the same region.

The results, as Mr Alcock points out, appear small, but this must be attributed to the poverty of the fauna and flora, every effort having been "made to get together as complete and representative a collection as possible." Six mammals, 37 birds, 4 fishes, 10 butterflies, and a few miscellaneous invertebrates were obtained, besides 105 phanerogamous and 10 cryptogamous plants. Four more mammals were seen, but no reptile nor batrachian was met with, despite careful search, and although specimens of both were obtained on the journey between Kashmir and the Pamir. All the fishes, except one loach, belong to the curious group of carps (the *Schizothoracinae* of McClelland), with enlarged imbricate scales at the base of the anal fin. This group appears to be peculiar to Central Asia.

In the list of the animals obtained on the road between Kashmir and the Pamir, a very few forms with Indian affinities occur, for instance, a *Trochilopterus* among the birds, but still the great majority are Palearctic species; even three earthworms are identified by Mr. Beedard as European. The Pamir fauna and flora show no trace of Indian affinities, but pertain strictly to the Central Asiatic phase of the Palearctic (or Holarctic) region. At the same time, now that we know the fauna and flora of the Pamir plateau well, their most striking feature is the distinction shown from the animals and plants of Tibet. There is no great difference between the physical features of the two areas; they are both from 12,000 to about 18,000 feet in height (the Tibetan

averaging rather the higher, but by not more than 2000 feet), and the two are completely united by the tableland of Western Tibet. Nevertheless very few of the animals or plants are identical, and the few that are appear to be forms of very wide range. Nor is this all, for so far as the mammalia, the best known and most important group, are concerned, the fauna of the bleak, barren plateau of Tibet appears to be considerably more numerous than that of the rather less bleak Pamir, despite the well-known rich pasture lands of the latter. Thus, taking the Ungulates alone, only two species, *Ovis poli*, Marco Polo's sheep, and *Capra sibirica*, the Asiatic ibex, are known from the Pamir, whilst in Tibet, the yak, Tibetan antelope (*Pantholops*), Tibetan gazelle, two if not three wild sheep (*Ovis hodgsoni*, *O. nahiru*, and probably *O. vignei*), an ibex, and the kiang (*Equus hemionus*) occur, without taking into account *Budorcas*, two species of *Cervus* and the musk deer, which are found in parts of the plateau. The same difference is found in other mammalia, thus the golden marmot, *Arctomys aureus*, of the Pamir replaces *A. himalayensis* and *A. robustus* of Tibet, and *Lepus tibetanus* to the westward represents the *L. pulchripes* and *L. hypsibius* of the great Eastern plateau.

As already stated the two plateaus, the Pamir and Tibet, are continuous, and are not separated from each other by any distinct elevation or depression. The cause of the marked difference in the fauna and flora needs explanation, and may not improbably be connected with the geological history of the two areas. It has been already shown that the specialisation of the Tibetan mammalian fauna probably indicates isolation during the latter portion of the Tertiary era, an isolation which can only be attributed to elevation. Whether it should be inferred that the elevation of the Pamir, which is believed to have been connected with the origin of the Himalayas, is of later geological date than that of Tibet, is a question that must be left to future geological explorers.

The geological observations in the present work are limited to petrological notes, the rocks found having been noted, and specimens brought away, which were examined by Mr Holland. This proceeding, like the proverbial carrying away of a brick as a sample of a house, though apparently approved by high geological authorities, is extremely unsatisfactory, and it is to Mr Holland's credit that he has been able to add one interesting fact, at all events, to previous observations. This is that certain rhyolites which are found on the Pamir are precisely the rocks that might be expected as the volcanic representatives of Stoliczka's "Central Gneiss," which Mr Holland agrees with General McMahon in regarding as intrusive. This "Central Gneiss" forms the axis of the Himalayas and, as Stoliczka showed, it occupies an extensive area on the Pamir. It is curious that no allusion to Dr Stoliczka's observations on the Pamir is to be found in Mr. Holland's notes.

In conclusion, it may be fairly stated that we are indebted to the Government of India and to Mr Alcock for a very useful addition to the facts hitherto known as to the distribution of Asiatic animals and plants. Mr. Alcock acknowledges the assistance given by Mr. Finn in determining the birds collected, and by M. de Nicéville for the Lepidoptera. Mr Duthie, who supplies the list

of plants, has adopted the admirable plan of giving under each species a brief note of its range, a most valuable addition in a paper of which the importance is chiefly distributional. The plates consist of photo-etchings well executed in the Survey of India Office, and represent fishes, reptiles and crustaceans, the rock structure of a biotite granite, and a view of an *Ovis polii* skin on a wall of rough stones amongst small orchards. The last is so good a plate, that it is impossible to help regretting that a more congenial background has not been selected.

W. T. B.

SOCIOLOGICAL SCIENCE

Outlines of Sociology. By Lester F. Ward. Pp. xii + 301. (New York: The Macmillan Company, 1898.)

MR. WARD'S little volume, with its clear thought and trenchant writing on more than one topic of current interest, will be welcomed by all students of sociology. It is a reprint of twelve chapters formerly contributed by the author to the *American Journal of Sociology* during the years 1895 to 1897. In the first six lectures, which bear the general title "Social Philosophy," Mr. Ward discusses the old question of the proper position of sociology in a systematic classification of the sciences. The general philosophical position adopted is that of Comte, but the author very properly restores anthropology and psychology to their lawful position in the scheme of the sciences between biology and sociology, and insists with great force upon the very special dependence of sociological on psychological science. The most interesting feature of this part of the book is Mr. Ward's able criticism of Mr. Herbert Spencer's favourite comparison of society to a huge biological organism. Following the lead of Prof. Huxley, he shows, by irresistible arguments, that it is not the whole biological organism, but only the nervous system which really corresponds to a society, and further, that society in its present state is at best a "very low form of organism."

"The most extreme socialist would shrink from the contemplation of any such absolutism as that exercised by the central ganglion of even the lowest of the recognised Metazoa. In order to find a stage comparable to that occupied by society with respect to the central control of the functions of life, it is necessary to go down among the Protozoa and study those peculiar groups of creatures that live in colonies so adapted, that, while the individuals are free to act as they please within certain limits, they are still imperfectly bound together by protoplasmic threads to such an extent that they are in a measure subordinate to the mass thus combined, and really act as a unit or body."

When conscious co-operation of society, as a whole, for its own welfare supersedes sporadic individual effort, and not before will there be a real parallelism between social institutions and the nervous structure of the higher animals.

In the second part of the book, which is entitled "Social Science," Mr. Ward describes the gradual evolution of such a higher form of social structure. Social institutions at first grow up unconsciously under the pressure of the mere "struggle for existence." As intelligence progresses this stage of mere "genesis" passes into the higher stage, called by Mr. Ward "telestis,"

unconscious growth gives place to the deliberate manufacture of institutions by conscious purposive action. Hitherto such conscious creation of social institutions has been the work of a few exceptional individuals, but in a higher stage of evolution we may expect it to take the form of "collective telestis," i.e. the deliberate co-operation of the community as an organised whole in the work of social amelioration.

Perhaps the most valuable part of Mr. Ward's book is that in which he discusses the differences between mere unconscious growth and deliberate constructive activity. It has been too much the fashion of sociologists in recent years to argue directly from biological analogies, forgetting that society is at least as much a machine as an organism, and that the presence in all but the lowest stages of social evolution of deliberate human purpose profoundly modifies the whole character of the evolutionary process. As Mr. Ward pithily phrases it, "the environment transforms the animal, but man transforms his environment," a remark which has an obvious bearing upon the application of evolutionary principles to the problems of ethics. Altogether the student who is not content with being told that society "evolves," but wishes to know how specifically social differs from merely biological evolution, will find Mr. Ward's last six chapters singularly luminous and suggestive. The get-up and typography of the book are generally worthy of commendation, but there are some ugly misprints of classical names. A. E. TAYLOR

OUR BOOK SHELF

A Text-book of Botany. By Dr. E. Strasburger, Dr. Fritz Noll, Dr. H. Schenck, Dr. E. F. W. Schimper; translated from the German by H. C. Porter, Ph.D. With 594 illustrations, in part coloured. (London: Macmillan and Co., Ltd., 1898.)

THE "Text-book of Botany" issued from the famous institute at Bonn has met with such favour on the part of teachers and students, that it is a matter of surprise that the translation of it into English should have been so long deferred. However it is certain to be extensively used, as the subject is handled from a comprehensive standpoint, and the authors have succeeded in hitting the happy mean between a too elementary and a too advanced treatment.

It is the more to be regretted that, as it was passing through the press, the emendations and corrections which have some time ago appeared in the third German edition were not incorporated in the present volume, which seems based on the first edition in the original language. It is, for example, surprising, and to a student confusing, to find elaborate figures and descriptions of centrospheres in dicotyledonous cells on p. 61, when it is known that the author of this part of the book (Strasburger) has long ago abandoned his belief in their existence, and in the current German text expressly denies their presence in these plants. It may also be doubted whether the book gains at all in value by the somewhat poor coloured illustrations of certain examples of flowering plants, although in this the publishers are but following the original. If, however, they could see their way to reduce the rather high price of the book at the expense of these really useless luxuries, both its own circulation and the temper of the purchaser would improve. For it is not a little remarkable to find a work which in Germany can be bought for 7 marks, costing in its English dress 18s. The book is intrinsically so good that it is to be hoped

that a more moderate price will place it within the means of many students who at present will certainly be debarred from possessing it, save through the intermediation of the second-hand bookseller

Automobiles sur Rails. By G. Dumont Pp 184 (Paris Gauthier-Villars et Fils Masson et C^{ie})

Régularisation du Mouvement dans les Machines By L. Lecornu Pp 217. (Paris Gauthier-Villars et Fils Masson et C^{ie})

THESE two volumes belong to the *Encyclopédie scientifique des Aide Mémoire*, and, like most of the volumes in this series, they contain concise statements of the subjects with which they deal. M. Dumont examines the various systems of horseless traction in use. He begins with steam motors, and then in successive short chapters describes compressed air motors, gas and oil motors, motors driven by carbon dioxide and by ammonia, cable traction, and electric motors. The descriptions are not detailed enough to be entirely satisfactory, nevertheless the volume contains a useful survey of the condition and methods of automobile traction.

M. Lecornu gives in his volume a detailed discussion of the motions of governors of indirect and direct action. His treatment of the various problems involved, and his theorems on the conditions of equilibrium of different governors will interest students of the mathematics and mechanics of machinery.

A Pocket Dictionary of Hygiene. By C. T. Kingzett, F.R.C., and D. Homfray, B.Sc. Pp 104. (London Baillière, Tindall, and Cox, 1898.)

THIS pocket-book is intended to be of assistance to medical and sanitary officers in their work, by providing them with concise information upon subjects comprehended in the theory and practice of hygiene. The amount of information given is somewhat unequal, and we should hardly have thought it necessary to include such definitions as "Adipose, fatty. Anhydrous, without water. Cardiac, pertaining to the heart. Caustic, any substance which destroys animal tissue. Combustion, the process of burning. Emanate, to issue or flow from. Morbid, diseased or unwholesome." &c. Hertz's name is spelt Herz, and Lenard is printed Lennard, in the description of Röntgen rays.

The Secret of the Poles. By Henry Campion Pp 48 (Birmingham White and Pike, Ltd., 1898.)

AMONG the views advanced by the author in this booklet are the following—The earth is hollow—there is a hollow region large enough to hide the moon and to spare—the earth's axis is hollow—it has two openings, one at each pole—meteoric swarms and ether are attracted through the axis at the south polar entrance, there producing the aurora australis, and after acting as fuel for the fire in the interior is shot out as a waste product at the north polar exit, where it produces the aurora borealis. The character of the book is sufficiently indicated by these extracts, which need no comment.

Wireless Telegraphy, popularly explained. By Richard Kerr, F.G.S. Pp xv + 111. (London Seeley and Co., Ltd., 1898.)

MR W. H. PREECE expresses his general approval of this little volume in a short preface; but at the same time he mentions that he does not accept any responsibility for the controversial points raised. The author explains the principles and practice of telegraphy without intervening wires in words which will be found intelligible by readers unfamiliar with electrical terms. His descriptions possess the merit of being popular in style, and the illustrations assist in brightening the text.

LETTERS TO THE EDITOR

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

Chance or Vitalism.

PROF JAPP'S exceedingly interesting address on "Stereochimistry and Vitalism" contains a direct challenge to those who, like myself, hold that we can at present only remain agnostic with regard to the problem of "the possibility or impossibility of living matter originating from dead matter by a purely mechanical process." Unfortunately the facts upon which he bases his view, that chemical compounds of one sided asymmetry cannot arise save under the influence of life, touch a field so much more familiar to him than to me, that it may seem presumption on my part to make one or two suggestions drawn more directly from my own sphere of work. Still, to the philosophical side of his reasoning I think Clifford, whom he challenges, might, perhaps, have been ready with some reply. I would first state what, I think, stripped of technical language, and represented by the simplest case, is Prof. Japp's standpoint.

(1) Optically active liquids are due to asymmetrical molecules.

(2) These asymmetrical molecules arise from the replacement in a symmetrical molecule of either a right hand or left-hand atom out of two equal atoms which are images of each other.

(3) No optically active substance can be formed unless there be a selection of purely right handed or purely left handed atoms, or, at any rate, unless there be a sensible majority of one or of the other.

(4) Some asymmetric solvents have a power of selective action on optically inactive mixtures of right-handed and left handed atoms, or, to use the technical term, of two enantiomorphs.

(5) No mechanical process (chemical or physical) could select a right handed as distinguished from a left handed atom in a symmetrical molecule, and so produce an asymmetric compound. Any mechanical force which acts on a symmetrical molecule is as likely to affect one atom in a molecule as its image. If I be the selecting of a right hand atom and II of a left hand atom, then, as Prof. Japp puts it

"The chances in favour of these two events being equal, the ratio,

$$\frac{\text{Number of occurrences of event I}}{\text{Number of occurrences of event II}}$$

will, if we are dealing with an infinitely great number of molecules, approximate to unity. We therefore obtain a mixture, optically inactive by inter molecular compensation."

Now, putting on one side any objections to Prof. Japp's reasoning arising from the fact that it is based on a purely geometrical hypothesis as to the constitution of molecules, which is also merely descriptive, for we can have no ultimate evidence of its actuality—I would draw attention to the fact that (5) is an appeal to the doctrine of chance, and that Prof. Japp tells us that the mechanical production of a left handed or right handed enantiomorph is an event like the tossing of a coin, of which the chances are precisely equal as to heads or tails. Now if Prof. Japp will toss twenty coins, ten heads and ten tails will undoubtedly be the most frequent result, but there will be a variation about this mean result, and if he goes on tossing long enough he will ultimately come to an instance of twenty heads or twenty tails alone. Cases in which there is a preponderance of heads or tails of a very sensible kind will not be very frequent. I take it that it is only a majority of left- or right-handed enantiomorphs which is required to produce an optically active substance. What majority might be easily ascertained by delicate experiments on the rotatory power of mixtures of dextro- and laevo acids which are mirror-images of each other. Now, according to Prof. Japp, chance is the factor at work in the production of optically inactive mixtures of right- and left-handed enantiomorphs. Hence, it may be in the course of indefinite ages, purely mechanical action must certainly have produced chemical compounds of one sided asymmetry with various degrees of rotatory power, due to the greater or less

¹ Such a geometrical hypothesis cannot give the dynamical explanation of rotatory polarisation required by the physicist, and therefore the "eminent physicist" quoted by Prof. Japp was, I venture to think, right in saying that an explanation of rotatory polarisation is still wanting.

frequency of the two enantiomorphs. We might even predict that if a chemist were to spend his life in the preparation of innumerable and smallest physically sensible amounts of a normally racemoid substance, he would with fine enough apparatus ultimately be able to detect some amount of rotatory polarisation. In nature, where during countless ages (and in the past probably more actively than at present) inorganic actions and reactions have taken place without man's aid, the production of chemical compounds of one sided asymmetry must, on Prof. Japp's view of the relation of mechanical action to chance, undoubtedly have taken place. Further, according to Prof. Japp's fourth principle, we may look upon such asymmetrical compounds when they have once arisen as "breeders," or endowed with a power of selecting their own kind of asymmetry from other racemoid substances. Let us put this further statement on one side, however, and content ourselves solely with dissent from Prof. Japp's view expressed in the words

"But the chance synthesis of the simplest optically active compound from inorganic materials is absolutely inconceivable. So also is the separation of two crystallised enantiomorphs under purely symmetric conditions."

On the contrary, if the theory expounded by Prof. Japp be correct, the inorganic origin of optically active compounds is not only conceivable, but it has a degree of probability which, how ever small, might be calculated when we know what is the minimum number of molecules in a physically just sensible solution, and what is the majority of enantiomorphs of one kind which will give a just measurable amount of rotatory polarisation.

It will indeed be a great gain if Prof. Japp's address calls more attention to this exciting subject, and leads to further experiment and research.

KARI PFARSON

The Moon's Course

THE annual course which the moon takes in company with the earth round the sun was to me a long time a great puzzle, as it is to many others, until one day I demonstrated it to myself by the simplest method. Those who have some smattering of the heavenly bodies generally fail in their attempt to draw the moon's orbit, they find no explanation in popular works, and even in books written by well known authors the subject of the moon's motion is altogether ignored. All that is found is a circle showing the moon's phases, and it is this circle which is fatal to the conception of the true orbit of the moon even very young readers see the impossibility of a dozen or thirteen circles surrounding the sun.

For myself, failing to find assistance in books, I readily solved the problem by a practical method. I took a piece of wire and placed a cork on each end. I then drew a line on the table and advanced one, which I called the earth, along the line; the other cork necessarily followed it, and at the same time circulated round the earth in accordance with another force or motion given to it. Beginning with the moon behind the earth and making it pass to the right, both advancing forward, the moon made a curve until it reached the front of the earth, and then the latter still advancing, took the moon with it, this came on its left side, and then making another curve on that side, again reached the front; the two curves completing the orbit round the earth.

My object in writing at the present moment is, that when so many persons are spending their holidays at the sea-side and there is much talk of the tides together with the moon, I take the opportunity of demonstrating by a similar method the moon's course on the sands. I make one person walk in a straight line, marking this with a stick, which he drags behind him, and I call him the earth. I then place another person, the moon, at a given distance from the other, telling him to advance also, and at the same time circulate round his companion. Beginning behind, and taking the right hand, he goes forward, making a curve until he gets to the front, then passes to the left side and forms another curve just as in the other experiment. The four quarters of the moon are in this manner seen, and if the second person continually faces the earth the moon's monthly revolution is also completed.

As these demonstrations are made on a plane, the experiment may also be shown in another way. I wind some wire thirteen times (the number of the lunar months) round a cylinder, and then take off the coil thus made. I pull it out into a helix and

join the ends of the wire. The course of the moon is shown in the spiral, although no correct proportions are attempted. This also gives some idea why the moon is sometimes seen on the horizon and sometimes at the zenith, the reason of which is a great difficulty to young people, as they find nothing about it in their books.

I make no pretence to be an astronomer or mathematician, and, indeed, it may be even a presumption to send this communication to a scientific journal, but if those who can teach fail to do so in popular books, there is no other method for the uninitiated to do the best for themselves. SAMUEL WILKS.

Grosvenor Street.

The Aurora of September 9

THIS evening, at about three minutes past eight, on looking out towards the south-west, I was struck by the appearance of a shaft of white light stretching from that direction upwards towards a point 10° or 20° south of the zenith, and immediately on reaching open ground, whence a wide view was obtained, became aware that a fine display of aurora borealis was in progress. The shaft of light successively appeared and disappeared at intervals of a few seconds, and each time further eastwards, but each section was separated from the last by a space of unilluminated sky, as if there were regular spaces in the course of the beam incapable of being set aglow. Very soon after passing overhead the illumination became faint and disappeared eastwards, but now a strong glow appeared again near the horizon under a cloud south west by west, and this rapidly grew upwards, repeating the phenomenon described in the first case. This occurred at least eleven or twelve times with little variation, except that the shaft became broader and more diffuse. The glow near the horizon south westwards was always followed by the passage of the light across the sky within 1 to 1½ min., and each travelling beam was separated from the last by an interval of 1½ to 2 min. Meanwhile the sky north westwards showed a pale white steady auroral light, which was at first attributed to the remains of twilight, but which continued to increase till about 8.30, when it was sufficiently strong to cast shadows and to show large print distinctly. This illumination extended slowly upwards from the north until it covered a great part of the sky up to the zenith, and seemed to be due to the luminosity of the great sheet of cirrus and cirrostratus which had covered the sky since 3.30 p.m., for it exactly imitated the distribution forms of the cloud which I had noted during the afternoon. This cloud, unilluminated, did not appreciably obscure the stars. The lacuna of dark interspaces, while the surrounding sky shone with pale light, resembled bands or puffs of dark smoke, but remained fixed in the same situation, and altogether the phenomenon was strangely persistent, the only evident changes being a gradual shifting from north west to north-east, and at about 9 p.m. a rosy streak north-eastwards. A little later fresh rays were shooting up from north-west by west, somewhat resembling those which an hour previously had emerged from south-west by west, but more steady and unbroken. At 9.55 a faint light was still to be seen in a north westerly direction. Two hours before this grand exhibition we had been able to get a good view of the large spot on the sun, the intervening bank of cirroform cloud making his appearance through a telescope more like that of the moon. I have not seen any authoritative statements as to interruption of telegraphic messages or other magnetic disturbances coincident with or preceding the visible aurora, but no doubt some effect must have been observed.

Dunrozel, Haslemere, September 9

ROLLO RUSSELL

A White Sea.

DURING the recent voyage of the P and O Co. s.s. *India* to London I had an opportunity (owing to the kindness of Captain Worcester) of witnessing what seems to be a rare phenomenon. The commander had seen it two or three times in the course of his experience. No one else on board knew anything about it, and I should be glad of a reference to any detailed description.

At 1.30 a.m. on the morning of August 22, in the Indian Ocean, the officer in charge saw ahead what seemed to be a low mist, and into which the vessel steamed. I was called about fifteen minutes later.

The whole sea was milk-white, much more luminous than the clear, starry sky, and there was a very definite horizon.

There was no moon, the wind was south west and light—the end of the monsoon; and although the sea was, as a matter of fact, breaking here and there, it appeared a calm white sheet, only disturbed by the displacement waves near the ship and a very occasional breaker elsewhere; showing through it were occasional flashes of the ordinary brilliant phosphorescence. It will therefore be seen that the luminosity of the “white sea” was rather less than that of a breaking wave with the same illumination. A bucket of water drawn showed nothing unusual. Samples with and without alcohol were preserved.

A fireball was thrown overboard, and burnt on the surface of the water; this was done in order to see if any fog or mist was present. There was an indication of anything of the kind.

On the port side of the ship is an aperture through which the surplus water from the bath tanks is constantly ejected, slightly warmed. This water, as it fell on to the sea, appeared much blacker than the sea, and floated for a few seconds as a black mass; unfortunately, the same shoot is used for the ashes at times. But the ejected water is quite white by daylight.

The appearance of the sea lasted about an hour, then faded, then brightened again, and was quite bright at daylight, 4.15 a.m.; so that it was seen throughout a distance of nearly fifty miles. A slight recurrence was observed the following night, when the monsoon was blowing more strongly.

At 3 o'clock on the 22nd, in the midst of the “white sea,” the latitude was $10^{\circ} 35' N$ and the longitude $63^{\circ} 25' E$; the temperature of the air was $77^{\circ} F$, that of the water $77^{\circ} F$. Specific gravity of the water by ship's instrument No. 1314 = 25.

I shall be glad to hand over the specimens of water to any one interested. JAMES W. BARRETT

22 Cavendish Square, September 13

Deep-Sea Dredging, and the Phosphorescence of Living Creatures, at Great Sea Depths

May I call attention to this most interesting subject, upon which so little is known, and with reference to the exploration of the bottom of tropical seas, *nothing is known*, though there is here a mine of natural history wealth probably of unexampled magnitude. In that interesting work on “The Depths of the Sea,” by Sir Wyville Thomson, published more than twenty years ago, we get a glimpse of a hitherto unworked zoological province, which creates a desire to know more from the richness and beauty revealed, where it would be least expected.

He writes—“We had a gorgeous display of luminosity, coming down the Sound of Skye, while dredging in 100 fathoms.

“The Pavonaria came up, resplendent with a pale lilac phosphorescence, like the flame of cyanogen gas—not scintillating, but constant and sufficiently bright to make every portion of a stem distinctly visible, and the stems were a metre long, fringed with hundreds of polyps; and from the number of specimens brought up, we must have passed through a luminous forest of them.”

“Among Echinoderms, *Ophiacantha spinulosa* was one of the prevailing forms, and we were greatly struck with the brilliancy of its phosphorescence. Very young *Ophiacantha* shone very brightly also.”

“At 344 fathoms, some of our hauls were taken late in the evening, and the tangles were sprinkled over with stars of the most brilliant uranium green. The light was not constant, nor continuous all over the stars, but sometimes it struck out a line of fire all round the disc, flashing or glowing up to the centre; then that would fade, and the whole five rays of *Ophiacantha spinulosa* would light up at the ends, and spread the fire inwards.”

“At 557 to 584 fathoms, many of the animals dredged were most brilliantly phosphorescent. In some places, nearly every thing brought up seemed to emit light, and the very mud itself was perfectly full of luminous specks. The Pinnatula, Virgularia, and Gorgonia, shone with a lambent white light, so bright that it showed quite distinctly the hour on a watch.”

“The light from *Ophiacantha spinulosa* was a brilliant green, coruscating from the centre of the disc, now along one arm, now along another; and vividly illuminating the whole outline of the star-fish.”

From a depth of 567 fathoms, a beautiful scarlet Urchin, *Echinus mucronatus*, was obtained. In the year 1846 Kjerfveit mentions having seen in Stockholm a Crustacean taken from the

depth of 1400 fathoms, of a bright colour. In 1869 and 1870 dredging was carried down to 2435 fathoms by H. M.'s ship *Porcupine*, and the fact that there is an abundant and characteristic invertebrate fauna at that great depth was placed beyond question; but the bottom of the deep sea that has been fairly dredged, may still be reckoned by the square yard; while every haul of the dredge, hitherto used, has brought to light new and unfamiliar forms.

In the number of NATURE for June 30 of this year, there is a most interesting article on deep sea fishing by means of a trap, an illustration of which is given. These traps are said to have been used at a depth of three thousand fathoms, with complete success. On one occasion a trap that had been lying on the bottom of the Mediterranean, at 700 fathoms depth, for twenty-four hours, brought up 1198 fish, called *Sinemchelys parasitica*. On another occasion, a new crab, one of the largest ever known, *Geryon affinis*, was brought up, and there were sixty-four specimens of it. All this shows how much remains to be done in this province of natural history. E. L. J. RIDSDALE

The Injection of Cocaine as a Remedy for Stings

As no one has answered the question asked by Sir J. F. Donnelly in your issue of September 8, will you allow me to say that the hypodermic injection of cocaine, or indeed its use in any form, is never quite free from risk. As with most other drugs there is an element of idiosyncrasy, which sometimes produces unexpected and unpleasant results. I believe these occur more frequently, when the drug is injected, than when it is simply applied to the mucous membrane, and when they do occur, they are very alarming. I know that some dentists have given up the practice of injecting cocaine into the gums before extraction on this account, and having been present once when it was done, I should not consent to it again. What we have to remember with regard to the use of all powerful drugs is this, that a few individuals under all conditions, and nearly all under certain conditions, are especially susceptible to their action, and that we cannot determine *a priori* either the individuals so predisposed, or the conditions, which render susceptible those not specially predisposed. These drugs must therefore be used with caution, and not be regarded as wholly innocuous.

I should say the hypodermic injection of cocaine into the tongue is undesirable, and only to be done if the pain is intense or the swelling such as to threaten life, in which case it would probably be useful. I would add that so far as I know no solutions of cocaine keep well. M. D., OXFORD

THE GEOGRAPHY OF THE UNITED STATES¹

THIS volume completes the description of the North American continent with the exception of Mexico, but, although an excellent account of the United States, it leaves North America itself still undescribed. The general reader, of course, will not miss what he has not been trained to expect; and, if he leaves the conception of geography as a science capable of systematic study out of account, the professed geographer will find much valuable material collected with discrimination and stated clearly and modestly. Indeed, except for an implication on the first page that the United States are in many respects more civilised than Canada, the English reader will find nothing to disturb his equanimity even in the account of the revolutionary war or the feats of the *Alabama*. Mr. Gannett writes always as a good American, but is ready to recognise the defects of his country when necessary, and careful to buttress all agreeable statements with statistics which more than prove them.

Of the arrangement of the matter it is impossible to speak with the same satisfaction. The chapters do not flow in the natural sequence desirable in a literary work,

¹ “Stanford's Compendium of Geography and Travel (New Issue) North America. Vol. II. “The United States.” By Henry Gannett, Chief Geographer of the United States Geological Survey. Maps and Illustrations. Pp. xvi + 456 (London: Edward Stanford, 1898).

nor are the subjects arranged in alphabetical order usual in a book for occasional reference. It is a little of a shock to turn from mineral resources to population, from great cities to the native Indians, and from commerce to Alaska, even although each chapter in itself is excellent reading.

Mr. Gannett was evidently anxious to resist the temptation of enlarging unduly upon his own special subject, and he has in our opinion gone to the opposite extreme, and lost an opportunity of showing how completely the structure of the country determined by its geology dominates the whole geography of the United States. The introductory chapter does contain a good deal of geology in relation to the configuration of the different natural regions, but the connecting links with the other distributions are wanting. It would be better in a book intended primarily for the general English reader to translate the statistics so freely given into the usual British units of weight and money; the "short tons" for coal and "long tons" for iron ore are puzzling, and make

establish electric power-houses at once for all needs. So, too, he shows that no country in the world possesses so many ruined cities as the United States—not only the abodes of the early mound-builders and cliff-dwellers, but ruins of yesterday, mushroom towns that teemed with busy thousands in a year, and were abandoned in a month on the failure of a mine or of a company, leaving only "a history of disappointed hopes, of hardships and struggles."

The movements of population are well treated, and a map showing the areas where more than 10 per cent of the population are foreign-born, and those where more than 10 per cent of the population are of negro race, displays the interesting fact that the former occupies the whole north and west, the latter the whole south-east, leaving a narrow belt between the two areas. The number of original statistical and physical maps is one of the most striking and satisfactory features of the book, and the illustrations also are admirably selected. At a time when the United States are entering on a new era

FIG. 1.—The Giant Cactus of the Arid Region

FIG. 2.—Buttes in the Plateau Region

comparison with other countries difficult. Besides, it would greatly assist the clear conception of such statistics if they were expressed in round numbers.

Apart from these possibilities for improvement, the book contains nothing which we cannot heartily praise. The revision of the text is very thorough, and we have not detected a single erratum.

Many of the topics are handled with surprising freshness, and many interesting points are brought out, such as the changed manner of life of the hardy fishers of the New England coast, who have found an easy and profitable calling as caterers for holiday-makers from the great cities. The author discusses the whole question of American cities, showing how the convenience of the rectangular plan has outweighed æsthetic considerations, and explaining the relative backwardness of the old cities of the east, compared with the new growths of the west, by the vast amount of capital locked up in such archaic conveniences as gas-works and horse or cable cars, while the untrammelled new municipalities can

of their national life, the publication of so accurate and impartial an account of that great country by one of its own citizens is peculiarly appropriate, and deserves a cordial welcome.

HUGH ROBERT MILL

THE BRITISH ASSOCIATION

THE concluding meeting of the British Association was held on Wednesday, September 14. Sir William Crookes occupied the chair, and the Mayor of Bristol (Sir R. H. Symes) and the High Sheriff were present, as well as the principal officers and members of the Association. The following report of the meeting is from the *Times*—

The proceedings were opened by the announcement that the general committee had been able to pass grants to the amount of 14857—an amount which was justified largely by the success of the present meeting.

Sir Norman Lockyer proposed that the thanks of the Association be given to the Mayor, the High Sheriff, the

executive committee, and the local officers. He said that the great success of the meeting was largely due to the efforts of those referred to in the resolution. Never before in his experience of the Association had local effort led to such absolute smoothness in the working of the machine. It was a pity that the work of the Association had been so hard as to prevent many members from seeing all the points of interest in this interesting city of Bristol. The magnificent educational establishments which crowded the city were themselves worthy of close attention, and at some future meeting the British Association might find Bristol at the head of some great southwestern University.

Prof. Schafer seconded the resolution.

Mr. James Scott (of Toronto), on behalf of the Canadian members, expressed high appreciation of the welcome which had been accorded to them.

The resolution was then carried with much enthusiasm.

The Mayor of Bristol, Mr. Howell Davis (chairman of the executive committee), Mr. Arrowsmith (local treasurer), and Mr. Arthur Lee and Dr. Bertram Rogers (local secretaries), each responded, Mr. Arrowsmith expressing his acknowledgments for the cheque for £20 which had been given by the Council of the Association towards the Colston Hall fund.

Prof. Rucker next moved a comprehensive vote of thanks to all public bodies and private persons who had contributed to the success of the meeting. He said that if the citizens of Bristol had not supported the local officers, the success of the meeting could not have been secured in so large a measure. As President of the International Committee of the Magnetic Conference, he was charged to convey the best thanks of the foreign members to the Association and to the local authorities for the extreme kindness of their reception.

Dr. Gladstone seconded the resolution, which was carried unanimously, the High Sheriff responding.

Sir John Evans moved a cordial vote of thanks to Sir William Crookes, President, for his admirable address and for his conduct in the chair. He prophesied, when introducing Sir William to the chair, that the Association would hear from him a remarkable address, and that prophecy had been amply justified. One of the most valuable portions of that address was that in which public attention was called to the fact that there was in our atmosphere an inexhaustible supply of nitrogen, and that means should be discovered for employing that nitrogen to increase the produce of the earth. Sir William Crookes had fulfilled with courtesy and distinction all the many and various duties which the past week had imposed upon him, and the thanks of the Association were cordially due to him.

Prof. Roberts Austen seconded the resolution, which was carried with enthusiasm.

Sir W. Crookes, in responding, said that he felt like an electrical switch-board—for really he was only the transmitter and distributor of these thanks to those whose help had been so material. He was especially grateful to the Mayor and Mayoress, whose hospitality had facilitated his work so greatly, and he regarded as one of the highest compliments ever paid to him the invitation to the remarkable smoking-symposium of the previous Friday evening. As for the President's office, the pace was getting too fast for human endurance; and in a short time the British Association would, if the work were to be got through at all, have to elect a young athletic man of five-and-twenty instead of a man over three-score years and ten.

Prof. Rucker announced that the number of tickets issued for the present meeting of the Association was 2446.

This concluded the proceedings. The next meeting will be held at Dover, and will commence on September 13, 1899.

SECTION D.

ZOOLOGY.

OPENING ADDRESS BY PROF. W. F. R. WELDON, M.A.,
F.R.S., PRESIDENT OF THE SECTION.

IN attempting to choose the subject of the address with which custom obliges your president to trouble you, I felt that I should have the best hope of interesting you if I decided to speak to you on the subject most interesting to myself. I therefore propose to discuss, as well as I can, the principal objections which are urged against the theory of Natural Selection, and to describe the way in which I think these objections may be met.

The theory of Natural Selection is a theory of the importance of differences between individual animals. In the form in which Darwin stated it, the theory asserts that the smallest observable variation may affect an animal's chance of survival, and it further asserts that the magnitude of such variations, and the frequency with which they occur, is governed by the law of chance.

Three principal objections are constantly brought forward against this theory. The first is that the species of animals which we know fall into orderly series, and that purely fortuitous variations cannot be supposed to afford opportunity for the selection of such orderly series, so that many persons feel that if the existing animals are the result of selection among the variable offspring of ancestral creatures, the variations on which the process of Natural Selection had to act must have been produced by something which was not chance.

The second objection is that minute structural variations cannot in fact be supposed to affect the death rate so much as the theory requires that they should. And it is especially urged that many of the characters, by which species are distinguished, appear to us so small and useless that they cannot be supposed to affect the chance of survival at all.

The third objection is that the process of evolution by Natural Selection is so slow that the time required for its operation is longer than the extreme limit of time given by estimates of the age of the earth.

Now the first of these three objections, the objection to fortuitous variation as the source of material on which Natural Selection can act, is very largely due to a misunderstanding of the meaning of words. The meaning of the word Chance is so thoroughly misunderstood by a number of writers on evolution that I make no apology for asking you to consider what it does mean.

Consider a case of an event which happens by chance. Suppose I toss a penny, and let it fall on the table. You will agree that the face of the penny which looks upwards is determined by chance, and that with a symmetrical penny it is an even chance whether the "head" face or the "tail" face lies uppermost. For the moment, that is all one can say about the result. Now compare this with the statements we can make about other moving bodies. You will find it stated, in any almanac, that there will be a total eclipse of the moon on December 27, and that the eclipse will become total at Greenwich at 10.57 p.m., and I imagine you will all feel sure, on reading that statement, that when December 27 comes the eclipse will occur, and it will become total at 10.57 p.m. It will not become total at 10.50 p.m., and it will not wait until 11.0 p.m. You will say, therefore, that eclipses of the moon do not occur by chance.

What is the difference between these two events, of which we say that one happens by chance, and the other does not? The difference is simply a difference of degree in our knowledge of the conditions. The laws of motion are as true of moving pence as they are of moving planets, but it happens that we know so much about the sun, and the earth, and the moon, that we know the circumstances which affect their relative positions very accurately indeed; so that we can predict within less than a minute the time at which the shadow of the earth will next fall upon the moon.

But the result of tossing a penny depends upon a very large number of things which we do not know. It depends on the shape and mass of the penny, its velocity and direction when it leaves one's hand, its rate of rotation, the distance of one's hand from the table, and so on. If we knew all these things before tossing the penny, we should be able to predict in each case what the result would be, and we should cease to regard pitch and toss as a game of chance.

As it is, all we know about these complicated conditions is that if we toss a penny for a number of times, the conditions

which give "heads" will occur about as often as the conditions which give "tails."

If you examine any event which occurs by chance, you will find that the fortuitous character of its occurrence always depends upon our ignorance concerning it.

If we know so little about a group of events that we cannot predict the result of a single observation, although we can predict the result of a long series of observations, we say that these events occur by chance. And this statement seems to me to contain the best definition of chance that can be offered.

If we use the word chance in this sense, we see at once that our knowledge of animal variations is precisely knowledge of the kind referred to in our definition of chance. We know with some certainty the average characters of many species of animals; but we do not know exactly the character of the next individual of these species we may happen to look at. So that in the present state of our knowledge it is *a priori* certain that the great majority of animal variations should occur by chance, in the sense in which we have used the phrase, and I will show you in a moment illustrations of the fact that they do so occur.

But before doing so, I would point out the difference between the sense in which we have used the word chance, and the sense in which it is used by many objectors to the theory of Natural Selection. Such epithets as *blind*, *lawless*, and the like, are constantly applied to chance; and a kind of antithesis is established between events which happen by chance, and those which happen in obedience to natural laws. In many German writings, especially, this antithesis between *Zufälligkeit* and *Gesetzmässigkeit* is strongly insisted upon, whenever organic variation is discussed.

This view of chance is not supported by experience, and indeed, if it could be shown that any thing in human experience were absolutely lawless, if it could be shown that in any department of nature similar conditions did not produce similar effects, the whole fabric of human knowledge would crumble into chaos, and all intellectual effort would be a profitless waste of time. There is not the slightest reason to believe that any such absolutely lawless phenomena do exist in nature, so that we need pay no further attention to the writers who assume that chance is a lawless thing.

But if chance is a perfectly orderly and regular phenomenon, then the question, whether animal variations occur by chance or not, can be settled by direct observation. I will now show you one or two examples of events which undoubtedly occur by chance, and then compare these with one or two cases of organic variation.

As events which occur by chance, I have taken the results of tossing twelve dice. My wife has spent some time during the last two months in tossing dice for you, and I will ask you to look at the results.

Her first record gives the number of dice showing more than three points in each of 4096 throws of twelve dice. There are, of course, six numbers on each of the dice; so that if all the dice were perfectly symmetrical and similar, the average number of dice with more than three points should be six in each throw of twelve. But dice are not symmetrical and similar. The points on the dice used were marked by little holes, scooped out of their faces, and the face with six such holes scooped out of it was opposite to the face with only one such hole, so that the face with one point was heavier than the face with six points; and therefore six was rather more likely to be uppermost than one. In the same way, two was opposite five; so that the five face was a little more likely to fall uppermost than the face with two points. Therefore, it is a little more likely that you will throw four, five, or six, in throwing dice, than it is that you will throw one, two, or three.

Accordingly, the average number of dice, in these 4096 throws, which had more than three points, was not six, but 6.135.

To show you that this excess of high points was due to some permanent property of the dice, she threw these twelve dice another 4096 times; and the average number of dice with more than three points was 6.139. A third series of trials gave an average of 6.104, and a fourth gave an average of 6.116.

You see that the difference between the highest and the lowest of these determinations is only about one half per cent., so that the mean result of such a series of fortuitous events can be determined with great accuracy.

And just as the mean of the whole series can be determined, so we can know with considerable accuracy how often any

possible deviation from the average result will occur. The degree of accuracy with which we can know this may be judged from Table I.

TABLE I.—Frequency with which Dice showing more than three Points were thrown in each of Four Series of Trials, the number of throws in each Series being 2^{12} = 4096.

Number of dice with more than 3 points	Most probable frequency for symmetrical dice	Observed frequencies			
		I	II	III	IV
12	1	0	1	0	1
11	12	11	13	8	14
10	66	71	86	61	66
9	220	257	246	241	241
8	495	536	540	513	586
7	792	847	836	846	861
6	924	948	913	948	866
5	792	731	750	802	728
4	495	430	446	420	474
3	220	198	198	182	204
2	66	60	55	51	67
1	12	7	12	13	6
0	1	0	0	1	0

You see that the results of the experiments agree fairly well with one another, and differ from the results most probable with symmetrical dice, in the way which the structure of the actual dice would lead one to expect. Throws which give seven, eight, or nine dice with more than three points occur too often, throws in which only two, three, or four dice have more than three points do not occur often enough. You see then that each of these results is orderly and regular, and that the four results agree very fairly among themselves, not only in the mean value of each of them, but in the magnitude and frequency of departures from the mean. That they differ from the results which would probably be obtained with symmetrical and similar dice is only to be expected, because the dice used are neither symmetrical nor similar.

You notice that this table is very nearly symmetrical, the most frequent result is that which lies in the middle of the series of possible results, and the other frequencies would, with perfect dice, be distributed symmetrically on each side of it; so that with perfect dice one would be as likely to throw five dice out of twelve with more than three points as one would be to throw seven, and so on.

This symmetry in the distribution of the results is only found when the chance of the event occurring in one trial is even. The next table shows the result of 4096 throws of twelve dice.

TABLE II.—Frequency of Sixes in 4096 throws of Twelve Dice

Number of sixes	Most probable number with symmetrical dice	Number observed
8	0.58	1
7	4.66	7
6	27.18	24
5	116.43	115
4	363.54	380
3	808.53	796
2	1211.44	1181
1	1102.56	1145
0	459.52	447

in which sixes only were counted. The chance against throwing six with any one of the dice is of course five to one; so that in throwing twelve dice you are more likely to throw two sixes than to throw any other number. But you see that the chance of throwing only one six is very much greater than the chance of throwing three; the chance of throwing none is greater than the chance of throwing four, and while there is a chance of throwing five, six, or more, of course it is impossible to throw less than none at all; so that the diagram is all askew. You see that this time, as before, the frequency with which any

number of sixes did actually occur was as near to the result most probably with perfect dice as the asymmetry of the actual dice allows one to expect.¹

These results will be enough to show you how absurd is the attitude which so many writers have taken up towards chance when discussing animal variation. The assertion that organic variation occurs by chance is simply the assertion that it obeys a law of the same kind as that which expresses the orderly series of results we have just looked at.²

That is a matter which can be settled by direct observation. But in order to express the law of chance in such a way that we can apply it to animal variation, we must make use of a trick which mathematicians have invented for that purpose.

It is a well-known proposition in probability that the frequency with which one throws a given number of sixes in a series of trials with twelve dice is proportional to the proper term in the expansion of $(\frac{1}{2} + \frac{1}{2})^{12}$. The values in this table were calculated by expanding this expression. But if I had wanted to show you the most probable result of experiments with 100 dice, I should not willingly have expanded $(\frac{1}{2} + \frac{1}{2})^{100}$.

The labour would be too enormous. Then, again, suppose we are given a number of results, and are not told how many dice were used, how are we to find out the power to which we must raise $(\frac{1}{2} + \frac{1}{2})$, since this depends on the number of dice?

Before applying the law of chance to variations in which we cannot directly measure the number of contributory causes (the analogue of the number of dice), we must find some way out of this difficulty.

The way is shown by this diagram (Fig. 1).

The rectangles in this diagram are proportional to the various terms of $(\frac{1}{2} + \frac{1}{2})^{12}$; and they represent the most probable result of counting the number of dice with more than three points in a series of trials with twelve dice. The heights of these rectangles were determined by expanding $(\frac{1}{2} + \frac{1}{2})^{12}$; but you notice the dotted curve which is drawn through the tops of them. The general slope of this curve is, you see, the same as the general slope of the series of rectangles; and the area of any strip of the curve which is bounded by the sides of a rectangle is very nearly indeed the same as that of the rectangle itself.

The constants upon which the shape of this curve depends are easily and quickly obtained from any series of observations; so that you can easily and quickly see whether a set of observed phenomena obeys the symmetrical law of chance or not.

A good many characters of animals do vary in this symmetrical way; and I show you one which will always be historically interesting, because it was one of the principal characters used to illustrate Mr. Galton's invaluable applications of the law of chance to biological problems. That is the case of human stature. The diagram (Fig. 2) shows the stature of 25,878 American recruits, and you see that the frequency with which each stature occurs is very close indeed to that indicated by the curve. So that variations in human stature do occur by chance, and they occur in such a way that variation in either direction is equally probable.

In cases where a variation in either direction is equally likely to occur, this symmetrical curve can be used to express the law

of distribution of variations. And the great difficulty in applying the law of chance to the treatment of other cases was, until quite lately, that the way of expressing asymmetrical distributions by a similar curve was unknown; so that there was no obvious way of determining whether these asymmetrical distributions obeyed the law of chance or not.

The form of the curve, related to an asymmetrical distribution of chances, as the curve before you is related to symmetrical distributions, was first investigated by my friend and colleague Prof. Karl Pearson. In 1895 Prof. Pearson published an account of asymmetrical curves of this kind, and he showed the way in which these curves might be applied to practical statistics. He illustrated his remarkable memoir by showing that several cases of organic variation could be easily formulated by the method he described, and in this way he made it possible to apply the theory of chance to an enormous mass of material, which no one had previously been able to reduce to an orderly and intelligible form.

In this same memoir Prof. Pearson dealt with another

FIG. 1.

problem in the theory of chance, which has special importance in relation to biological statistics. It has doubtless occurred to many of you that the analogy between the complexity of the results obtained by tossing dice, and the complexity of events which determine the character of an animal body, is false in an important respect. For the events which determine the result, when we throw a dozen dice on the table, affect each of the dice separately; so that if we know that one of the dice shows six points, we have no more reason to suppose that another will show six points than we had before looking at the first.³ But the events which determine the size or shape of an organ in an animal are probably not independent in this way. Probably when one event has happened, tending to increase the size of an arm or leg in an embryo, it is more likely than it was before that other events will happen leading to increased size of this arm or leg. So that the chances of variation in the size of a limb would be represented by a law similar to that which expresses the result of throwing dice, but different from it. They would more nearly resemble the result of drawing cards out of a pack. Suppose you draw a card out of a pack. It is an even

³ That is to say, if we know beforehand that the dice are symmetrical.

¹ It is unfortunate that I chose dice as instruments in these experiments. Dice are not only sensibly asymmetrical, but any ordinary dice are sensibly *dextrorotatory*, so that the result most probable with any actual dice is not given by a simple binomial expansion. The result theoretically most probable for the actual dice used could not be determined without very careful measurement of the dice themselves, and I was unable to attempt measures of the requisite accuracy. All that the records show, as they stand, is the amount of agreement between four successive observations of a fortuitous event.

² The law is not, however, identical in the two cases, see *infra*.

chance whether you draw a red card or a black one. Suppose you draw a red card, and keep it. The chance that your second card will be red is not so great as the chance that it will be black; because there are only twenty five red cards and twenty-six black cards left in the pack.

Now Prof. Pearson has shown how to deal with cases of this kind also, and how to determine, from the results of statistical observation, whether one is dealing with such cases or not.

I am no mathematician, and I do not dare even to praise the mathematical process by which this result was achieved. I will only say that it is experimentally justified by the fact that most statistics relating to organic variation are most accurately represented by the curve of frequency which Prof. Pearson deduces for the case where the contributory causes are mutually interdependent.

The first case of an asymmetrical distribution in animals which I ask you to look at is the frequency of variations in the size of part of the carapace of shore crabs. The crabs measured were 999 females from the Bay of Naples. In this case the distri-

series of deviations from the mean length of the antero-lateral margin is as definite a character of the crabs as the mean itself; and in every generation a series of deviations from the mean is regularly produced, according to a law which we can learn if we choose to learn it.

Now suppose it became advantageous to the crabs, from some change in themselves or in their surroundings, that this part of their carapace should be as long as possible. Suppose the crabs in which it was shorter had a smaller chance of living, and of reproducing, than the crabs in which it was longer.

Suppose that crabs in which this dimension is longest were as much more productive than those in which it was shortest, as the most prolific marriages are more fertile than the least prolific marriages among ourselves. Prof. Pearson has pointed out that half the children born in England are the offspring of a quarter of the marriages. If we suppose the productiveness among crabs to vary as much as it does among ourselves, only that in crabs the productiveness is greater, the greater the length of this bit of the carapace, then half of the next

FIG. 2.—Diagram showing the height (in inches) of each of 25,878 American recruits

tion of variations (see Fig. 3) is very nearly symmetrical, and in an account of these crabs which I wrote before Prof. Pearson's memoir was published, I treated them as symmetrical. The curve actually drawn on the diagram is one constructed by Prof. Pearson himself from the data given by my measurements of the crabs, and it fits the observations very sensibly better than the symmetrical curve. So that this dimension of a crab's carapace does vary by chance, but the chance of a given deviation from the mean length is not quite the same in both directions.

Now, admitting for the moment that these differences in the length of a part of the crab's carapace can affect the crab's chances of survival, you see that natural selection has abundant material on which to work. The production of this regular

generation of crabs will be produced by that quarter of the present generation in which the antero-lateral margin is longest. And as the offspring will inherit a large percentage of the parental character, the mean of the race may be sensibly raised in a single generation.

This view of the possible effect of selection seems to have escaped the notice of those who consider that favourable variations are of necessity rare, and likely to be swamped by intercrossing when they do occur. You see that in this case there are a few individuals considerably different from the mean in either direction, and a very large number which differ from the mean a little in either direction. If such deviation be associated with some advantage to the crabs, so that crabs which possess such abnormality are more fertile than those which do not, it is a certainty that the mean character of the next generation will change, if only a little, in the direction advantageous to the race, and the opportunity for selective modification of this kind to occur in either direction is very nearly the same.

¹ Even the distribution of human stature, which has been so successfully treated by the older, so-called "normal" curve, is more accurately represented by a curve of Prof. Pearson's type, but in this case the difference between the two is so slight as to be inappreciable for all practical purposes, so that Mr. Galton's practice and Prof. Pearson's theory are alike justified.

In the next case, this is not true

The diagram (Fig. 4) represents the number of female swine, out of a batch of two thousand examined in Chicago, which have a given number of Müllerian glands in the right fore leg

FIG. 3.—Diagram showing the magnitude of the utero-lateral margin (in terms of carapace length) in 999 female shore crabs from Naples

The distribution is much more skew than in the case of the crabs, and you see again the very beautiful way in which Prof. Pearson's curve expresses it. You see that the range of variation is much greater on one side of the mean than on the other, and the selective destruction necessary in order to raise the mean number of glands by one would be very different from the amount of destruction necessary in order to lower the mean by one. Further, the mean number of glands in these pigs is $3\frac{1}{2}$; the number which occurs oftenest, the "modal" number as Prof. Pearson calls it,¹ is three. Now it is impossible to lower this number till it is less than 0, so that it can only be diminished by three, but it is conceivable that it should be increased by more than three. So that the amount of selective destruction required in order to change either the mean or the modal character of these pigs in one direction, would be greater than the amount required, in order to produce a change of equal magnitude in the opposite direction, and the

¹ All attempts to confine the word "average" to the most frequently occurring magnitude, and the word "mean" to the arithmetic mean of the series, have failed to secure support. Therefore Prof. Pearson's proposal to call the value which occurs oftenest the "mode" is very useful.

amount of possible change is greater in one direction than in the other

Now let us pass on to another example

Table III shows the variation in the number of petals in a race of buttercups studied by Prof. de Vries. You see that the most frequent

TABLE III.—Prof. Pearson's expression for the variation in the race of buttercups derived by Prof. de Vries

No. of petals.	5	6	7	8	9	10	11
Observed frequency	13	33	27	27	2	1	0
Pearson's theory	13.9	40.5	26.6	9.6	3.4	0.8	.2

number of petals is five, and that no buttercups whatever have more than five, and here again you see the way in which Prof. Pearson's formula fits the observations

FIG. 4.—Diagram showing the number of Müller's glands in each of 1000 male swine

You see that if this diagram (which is based on very few specimens) really represents the law of variability in these buttercups, no amount of natural or other selection can produce a race with less than five petals out of them. While it is conceivable that selection might quickly raise the normal number of petals, it could not diminish it, unless the variability of the race should first change.

These examples, which are typical of others, must suffice to show the way in which the theory of Chance, as developed by Prof. Pearson, can express the facts of organic variation.

I think you will agree that they also show the importance of investigating these facts. For of the four characters we have examined, we have seen that two, namely human stature and the antero-lateral carapace length of *Carcinus maenas*, vary so as to afford nearly equal material for selective modification in either direction, one character, the number of Muller's glands in swine, offers distinctly greater facility for selective modification in one direction than in the opposite direction; and in the last character, the number of petals in a race of buttercups appears to offer scope for modification in one direction only, at least by selection in one generation.

Knowledge of this kind is of fundamental importance to the theory of Natural Selection. You have seen that the new method given to us by Prof. Pearson affords a means of expressing such knowledge in a simple and intelligible form; and I, at least, feel very strongly that it is the duty of students of animal evolution to use this new and powerful engine which Prof. Pearson has provided, and to accumulate this kind of knowledge in a large number of cases.

I know that there are people who regard the mode of treatment which I have tried to describe as merely a way of saying, with a pompous parade of arithmetic, something one knew before. This criticism of Prof. Pearson's work was actually made to me the other day by an eminent biologist, whose name I will not repeat. If there be any here who hold such an opinion, I would ask them to read Mr. Francis Galton's *Essays on Heredity*; where a simple and quite unexpected relation between parents and offspring is shown to be a direct consequence of the fact that they vary by chance. This is the first and the most striking deduction from the mathematical theory of organic variation, but it is not the only one. It is enough, however, to show that the new method is not only a simple means of describing the facts of variation, which facts very few people knew before, but it is a powerful instrument of research, which ought to be quickly and generally adopted by those who care for the problems of animal evolution.

I think I have said enough to convince you how entirely Prof. Pearson's method promises to confirm the assertion that organic variation obeys the law of chance.

The other objections to Darwin's theory are not so easily answered. It is said that small variations cannot be supposed to affect an animal's chance of life or death, but few persons have taken any pains to find out in any given case whether the death-rate is in fact affected by small variations or not. It is said that the process of Natural Selection is so slow that the age of the earth does not give time for it to operate, but I know of few cases in which any attempt has been made to find out by actual observation how fast a species is really changing.

I can only attempt to discuss the importance of small variations, and the rate of organic change, in the one case which I happen to know. The particular case I have myself studied is the variation in the frontal breadth of *Carcinus maenas*.

During the last six years my friend, Mr. Herbert Thompson, and I have studied in some detail the state of this character in the small shore-crabs which swarm on the beach below the laboratory of the Marine Biological Association at Plymouth.

I will show you that in those crabs small changes in the size of the frontal breadth do, under certain circumstances, affect the death rate, and that the mean frontal breadth among this race of crabs is, in fact, changing at a rate sufficiently rapid for all the requirements of a theory of evolution.

In Table IV you see three determinations of the mean frontal breadth of these crabs, expressed in terms of the carapace-length taken as 1000. You see that the mean breadth varies very

1 Of course we know that selection does change the variability of a race.
2 In 1894 I gave an account of the variation of this dimension in female specimens of various sizes (*Ray Soc Proc.*, vol. LVII) and I put forward an hypothesis of the amount of selective destruction due to variation in this character. This hypothesis neglected several important facts which I now know, and was open to other objections. I desire to replace it by the results of the observations here recorded.

rapidly with the length of the crab, so that it was necessary to determine it separately in small groups of crabs, such that the length of no two crabs in a group differed by more than a fifth of a millimetre. The first column of the table shows you the mean frontal breadth of twenty-five such groups, between 10 and 15 millimetres long, collected in 1893. These crabs were measured by Mr. Thompson. The second column shows you the mean frontal breadth in twenty-five similar groups of crabs, collected in 1895, and also measured by Mr. Thompson. You see that in every case the mean breadth in a group of crabs collected in 1895 is less than it was in crabs of the same size collected in 1893. The third column contains the result, so far as it is yet obtained, of my own measurement of crabs collected this year. It is very incomplete, because the 1895 crabs were collected in August and September, and I was anxious to compare them with crabs collected this year at the same season, so that there has not yet been time to measure the whole series. The measurements are sufficient, however, to show that the same kind of change has taken place during the last three years as that observed by Mr. Thompson in the interval between 1893 and 1895. Making every allowance for the smallness of the numbers so far measured this year, there is no doubt whatever that the mean frontal breadth of crabs from this piece of shore is considerably less now than it was in 1895 among crabs of the same size.

TABLE IV.—The Mean Frontal Breadth ratio of Male *Carcinus maenas* from a particular patch of beach in Plymouth, in the years 1893, 1895, and 1898.

Length of carapace	Mean frontal breadth in terms of carapace length = 1000			
	1893 (Thompson)	1895 (Thompson)	1898 (Weldon)	No. of crabs in the 1898 group
10.1	816.17	809.08	—	—
10.3	812.06	804.82	—	—
10.5	807.37	803.27	—	—
10.7	803.96	801.69	—	—
10.9	805.07	799.47	—	—
11.1	802.51	794.12	784.25	4
11.3	798.18	792.38	787.36	11
11.5	797.19	788.83	784.00	9
11.7	794.28	785.29	782.44	16
11.9	791.45	786.53	780.09	11
12.1	788.38	780.61	775.25	16
12.3	783.98	779.50	773.42	12
12.5	783.49	776.50	767.00	11
12.7	783.38	773.43	774.43	14
12.9	777.38	771.53	764.67	15
13.1	776.63	771.61	760.13	16
13.3	774.66	766.21	761.29	7
13.5	766.91	763.96	759.56	16
13.7	767.63	764.00	757.00	16
13.9	763.73	759.40	756.10	10
14.1	758.94	757.00	744.00	13
14.3	756.90	755.77	747.86	7
14.5	762.60	754.45	744.44	9
14.7	753.00	749.84	739.22	8
14.9	751.32	748.03	742.83	6

These results all relate to male crabs. The change in female crabs during this time has been less than the change in male crabs, but it is, so far as my measurements at present permit me to speak, going on in the same direction as the change in male crabs.

I think there can be no doubt, therefore, that the frontal breadth of these crabs is diminishing year by year at a rate which is very rapid, compared with the rate at which animal evolution is commonly supposed to progress.

I will ask your patience for a little while longer, that I may tell you why I feel confident that this change is due to a selective

1 I shall, of course, consider it my duty to justify this statement by more extensive measurement as soon as possible. In the meantime I may say that I have measured other small groups of crabs, male and female, from the same place, at different seasons of the years 1896-98, and the results agree with those recorded in the table.

destruction, caused by certain rapidly changing conditions of Plymouth Sound.

If you look at the chart, you will see that Plymouth Sound is largely blocked up, and its communication with the sea is narrowed by a huge artificial breakwater, about a mile long, so that the tidal currents enter it and leave it only by two openings. This huge modern barrier has largely changed the physical conditions of the Sound.

On either side of Plymouth itself a considerable estuary opens into the Sound, and each of these estuaries brings down water from the high granite moorlands, where there are rich deposits of china clay. Those of you who know Dartmoor will remember that in rainy weather a great deal of china clay is washed into the brooks and rivers, so that the water frequently looks white and opaque, like milk. Much of this finely divided china clay is carried down to the sea; and one effect of the breakwater has been to increase the quantity of this fine silt which settles in the Sound itself, instead of being swept out by the scour of the tide and the waves of severe storms.

So that the quantity of fine mud on the shores and on the bottom of the Sound is greater than it used to be, and is constantly increasing.

But this is not all. During the forty or fifty years which have gone by since the breakwater was completed, the towns on the shores have largely increased their population; the great dockyard at Devonport has increased in size and in activity, and the ships which visit the Sound are larger and more numerous than they were. Now the sewage and other refuse from these great and growing towns and dockyards, and from all these ships, is thrown into the Sound, so that while it is more difficult than it used to be for fine silt to be washed out of the Sound, the quantity thrown into it is much greater than it was, and is becoming greater every day.

It is well known that these changes in the physical conditions of the Sound have been accompanied by the disappearance of animals which used to live in it, but which are now found only outside the area affected by the breakwater.

These considerations induced me to try the experiment of keeping crabs in water containing fine mud in suspension, in order to see whether a selective destruction occurred under these circumstances or not. For this purpose, crabs were collected and placed in a large vessel of sea-water, in which a considerable quantity of very fine china clay was suspended. The clay was prevented from settling by a slowly moving automatic agitator; and the crabs were kept in under these conditions for various periods of time. At the end of each experiment the dead were separated from the living, and both were measured.

In every case in which this experiment was performed with china clay as fine as that brought down by the rivers, or nearly so, the crabs which died were on the whole distinctly broader than the crabs which lived through the experiment, so that a crab's chance of survival could be measured by its frontal breadth.

When the experiment was performed with coarser clay than this, the death-rate was smaller, and was not selective.

I will rapidly show you the results of one or two experiments. The diagram (Fig. 5) shows the distribution of frontal breadths, about the average proper to their length, in 248 male crabs treated in one experiment. Of these crabs, 154 died during the experiment, and 94 survived. The distribution of frontal breadths in the survivors is shown by the lower curve in the diagram, and you see that the mean of the survivors is clearly below the mean of the original series, the mean of the dead being above the original mean.

Two other cases, which are only examples of a series in my possession, show precisely the same thing.¹

These experiments seemed to me to show that very finely

¹ It is impossible in this place to give a full account of the experiments referred to, and a multiplication of mere small scale diagrams seems useless, so that only one of those exhibited when the address was delivered is here reproduced.

divided china clay does kill crabs in such a way that those in which the frontal breadth is greatest die first, those in which it is less live longer. The destruction is selective, and tends to lower the mean frontal breadth of the crabs subjected to its action. It seemed to me that the finer the particles used in the experiments, that is to say, the more nearly they approached the fineness of the actual silt on the beach, the more selective their action was.

I therefore went down to the beach, where the crabs live, and looked at the silt there. This beach is made of moderately small pieces of mountain limestone, which are angular and little worn by water. The pieces of limestone are covered at low tide with a thin layer of very fine mud, which is much finer than the china clay I had used in my experiments, and remains suspended in still water for some time. Under these stones the crabs live, and the least disturbance of these stones raises a cloud of very fine mud in the pools of water under them. By washing the stones of the beach in a bucket of sea water, I collected a quantity of this very fine mud, and used it in a fresh series of experiments, precisely as I had before used china clay, and I obtained the same result. The mean frontal breadth of the survivors was always smaller than the mean frontal breadth of the dead.

I think, therefore, that Mr. Thompson's work, and my own, have demonstrated two facts about these crabs, the first is that their mean frontal breadth is diminishing year by year at a measurable rate, which is more rapid in males than in females, the second is that this diminution in the frontal breadth occurs in the presence of a material, namely, fine mud, which is increasing in amount, and which can be shown experimentally to

FIG. 5.—Diagram showing the effect of china clay upon 248 male crabs. The upper curve shows the distribution of frontal breadths in all these crabs, the dotted curve the distribution of frontal breadths in the survivors. The dotted line shows the mean of the survivors, the line D the mean of the dead.

destroy broad-fronted crabs at a greater rate than crabs with narrower frontal margins.

I see no shadow of reason for refusing to believe that the action of mud upon the beach is the same as that in an experimental aquarium, and if we believe this, I see no escape from the conclusion that we have here a case of Natural Selection acting with great rapidity because of the rapidity with which the conditions of life are changing.

Now, if we suppose that mud on the beach has the same effect upon crabs as mud in an aquarium has, we must suppose that every time this mud is stirred up by the water, a selective destruction of crabs occurs, the broad-fronted crabs being killed in greater proportion than the narrow-fronted crabs.

Therefore, if we could take a number of young crabs, and protect them through a certain period of their growth from the action of this selective mud, the broad-fronted crabs ought to have as good a chance of life as the rest, and in consequence the protected crabs should contain a larger percentage of broad individuals than wild crabs of the same age, and the mean frontal breadth of such a protected population ought to be greater, after a little time, than the mean frontal breadth of wild crabs, in which the broad individuals are being constantly destroyed.

It is difficult to perform this experiment, because one cannot know the age of a crab caught on the shore. But so far as one can judge the age of a crab by its length, I can show you that the thing which ought to happen, on the hypothesis that such selective destruction is going on, does actually happen.

I established an apparatus consisting of some hundreds of

numbered glass bottles, each bottle being provided with a constant supply of clean sea-water by means of a system of glass syphons. Into each of these bottles I placed a crab from the beach. After a considerable number of deaths had occurred, a series of crabs was finally established, each crab living in a numbered bottle, until it had cast its shell. The process of moulting involves no distortion of the carapace, which could affect the measurements concerned, and therefore each cast shell was carefully measured. The measurements of these shells were carefully compared with measurements of wild crabs of the same size, and the mean frontal breadth of these shells was a little less than the mean breadth in wild crabs of corresponding length.¹

After each crab had moulted, it was left in its bottle until it had grown and had hardened a new shell. It was then killed and measured, and the measurements obtained were compared with measurements of wild crabs of corresponding size. This time the captive crabs were unmistakably broader than wild crabs of their own size, and there were a few of the protected crabs which were very remarkably broad. The distribution of abnormalities before and after moulting is shown in Fig. 6.

This is precisely the result which we ought to have obtained, if the hypothesis suggested by the study of mud were true. By protecting crabs through a period of their growth, we ought to raise the mean frontal breadth, and to obtain a greater percentage of abnormally broad crabs, and that is what we have seen to occur.

Of course, this experiment by itself is open to many objections. The estimate of age by size is a dangerous proceeding, and it is difficult to exclude the possibility that confinement in a bottle may directly modify a crab during the crucial period of

It would take too long to go into that matter now, and I shall not attempt to do so. I will only now ask you to consider one or two conclusions which seem to me to follow from what I have said.

I hope I have convinced you that the law of chance enables one to express easily and simply the frequency of variations among animals, and I hope I have convinced you that the action of natural selection upon such fortuitous variations can be experimentally measured, at least in the only case in which any one has attempted to measure it. I hope I have convinced you that the process of evolution is sometimes so rapid that it can be observed in the space of a very few years.

I would urge upon you in conclusion the necessity of extending as widely as possible this kind of numerical study. The whole difficulty of the theory of Natural Selection is a quantitative difficulty. It is the difficulty of believing that in any given case a small deviation from the mean character will be sufficiently useful or sufficiently harmful to matter. That is a difficulty which can only be got rid of by determining in a number of cases how much a given variation does matter; and I hope I have shown you that such determination is possible, and if it is possible, it is our duty to make it.

We ought to know numerically, in a large number of cases, how much variation is occurring now in animals. We ought to know numerically how much effect that variation has upon the death rate, and we ought to know numerically how much of such variation is inherited from generation to generation. The labours of Mr. Galton and of Prof. Pearson have given us the means of obtaining this knowledge, and I would urge upon you the necessity of obtaining it. For numerical knowledge of this kind is the only ultimate test of the theory of Natural Selection, or of any other theory of any natural process whatever.

SECTION G

MECHANICAL SCIENCE

OFFERING ADDRESS BY SIR JOHN WOLFE BARRY, K.C.B., LL.D., F.R.S., PRESIDENT OF THE SECTION.

APART from all the other considerations which so favourably affect this Congress, I think, so far as Section G is concerned, that we are fortunate in meeting in this ancient city, which has so much of special interest for engineers and for others interested in applied science.

(1) I propose, therefore, to say a few introductory words about Bristol and its neighbourhood from the point of view of this section of the Association, but it is far from my intention to either criticise the past work of the Corporation in relation to their dock enterprises or to volunteer advice to them with respect to possible works of improvement.

Bristol is, at this moment, of great commercial importance, as indicated by the value of its imports and exports, and occupied an even more important relative position among British ports at a time when the ports of Liverpool, Glasgow, Cardiff, or Southampton were almost, or altogether undeveloped. So far as Customs Revenue is concerned Bristol now stands third, and in regard to the gross value of her sea-borne trade she is thirteenth among ports of the United Kingdom.

It is unnecessary, and it would be foreign to the objects of Section G, to attempt to trace the economic reasons which have caused the long continued importance of Bristol, or to account for the rapid growth of other ports more or less competitive with her. All such causes are to be found, at least to a great extent, in considerations apart from the merely physical characteristics of the sea, river, or land at the various sites, as, for example, in proximity to markets or centres of production, in situation relatively to population or to means of distribution, in individual or collective enterprise, in enlightened or unenlightened administration.

These circumstances have, in truth, at least as much if not more influence in determining the history and prosperity of ports than what are termed natural advantages of respective sites, by which I mean such matters as protection from winds

FIG. 6.—Distribution of abnormality of frontal breadth ratios in 54 female crabs before and after moulting in captivity. The continuous line shows the distribution before, the dotted line after moulting.

moulting, and so on. All these points would have to be discussed at greater length than your patience would bear, before we could accept this experiment by itself as a proof that some selective agent exists on the shore, which is absent from the bottles. At the same time, the result of this experiment is exactly what we should expect to find if such a selective agent did exist, and so it is in complete harmony with the evidence already put before you.

Of course, if the observed change in frontal breadths is really the result of selection, we ought to try to show the process by which this selection is effected.

This process seems to be largely associated with the way in which crabs filter the water entering their gill chambers. The gills of a crab which has died during an experiment with china clay are covered with fine white mud, which is not found in the gills of the survivors. In at least 90 per cent of the cases, this difference is very striking, and the same difference is found between the dead and the survivors in experiments with mud.

I think it can be shown that a narrow frontal breadth renders one part of the process of filtration of water more efficient than it is in crabs of greater frontal breadth.

¹ This was probably due to the death rate during acclimatization being selective. It was very difficult to keep the apparatus clean, and the deaths which occurred were in most cases due to the presence of putrescent bits of food, which had not been removed.

A subsequent experiment was made with the same apparatus, in which crabs were kept in purified water until a large percentage had died, and the mean frontal breadth of the survivors was found to be distinctly less than the mean frontal breadth of the dead.

and currents, depth of water in the port itself and in its approaches from the sea, the possession of soil adapted to the foundations of docks or quays, and ready access to suitable materials for cheap and efficient construction.

While recognising to the full the great advantages of such physical endowments in the development of a great port, one cannot but remember that they form only part of the problem, and that the business of engineers is to modify and direct the great forces and characteristics of nature for the use and convenience of mankind. We have, in fact, to make the best of a locality which may or may not be promising in the first instance, and history shows us that there are few places which are hopeless for our purposes. Thus while, on the one hand, we see many harbours in this country which inherit from nature every feature to be desired for the establishment of a port, but which remain useless for that object, so, on the other hand, we find many of the great centres of trade established in situations which possessed no such advantages, and where almost everything has had to be supplied by painful exertion and great expenditure.

As examples of these facts, I may point to the remarkable progress of many commercial ports situated in localities which were originally the reverse of promising from an engineering point of view—to Glasgow, where twenty six millions sterling in value of exports and imports are annually dealt with in ships of the largest draught, though it is placed on a river which only fifty years ago was nearly dry at low water for a distance of ten miles below the present docks—to Newcastle, with a present trade of 13½ millions sterling, which within the memory of this generation was approached by a shallow river, entering a much-exposed part of the North Sea over a dangerous sand bar. Sixty years ago the Tyne could only receive (and that only at high water) a small class of coasting vessels, whereas it is now navigable for deep draughted vessels for a distance of thirteen miles from the sea. The break waters also at Tynemouth, which have been constructed under great difficulties on a coast without a single natural encouraging characteristic, not only make a valuable harbour of refuge, but have, practically speaking, removed the external bar.

In a similar way, as evidence of the truth of my proposition, I might point to a multitude of other instances, to the great docks of Buenos Ayres, which city, when I knew it twenty years ago, could not be approached within seven or eight miles by sea going ships of fifteen or sixteen feet draught, to Calcutta, dependent on the dangerous navigation of the Hooghly, including the dreaded James and Mary shoals, to the creation of the port of Manchester, forty five miles from the sea, approached by a tide locked canal which has cost thirteen or fourteen millions of money in its construction, to the great recent developments of Rouen, Dunkirk, Antwerp, and Amsterdam, to the improvements of the Danube and the Mississippi. In all of these cases the natural characteristics of the localities were quite unsuited to the requirements of an advancing trade in modern vessels, but the inexorable demands of commercial shipping have created the supply, at the hands of engineers, of improvements and modifications of nature, which are so large and important that, to an unprofessional eye, they might now almost appear, at least in some of the cases which I have mentioned, to be physical characteristics of the locality.

I think that we may safely say that trade will produce the required accommodation, and that accommodation in itself will not create or attract trade.

Bristol is a case in point, and it is interesting to us at this meeting to note, however briefly, some of the important works which have altered and are altering its capacity as a port. At the end of last century Bristol and its capabilities were, as they have been almost ever since, the battlefield of civil engineers, and we know that reports and projects were made by most of the men who were then recognised as authorities. The diversion of the river Avon and the construction of the floating harbour of Bristol, which were carried out under the advice of William Jessop in the years from 1804 to 1809, were boldly conceived and ably executed. The result of the diversion of the Avon by means of what is still known as the New Cut enabled the old course of the river to be made into a floating harbour of about 71 acres, of which 57 acres are available for vessels of considerable size. The total cost seems to have been about 600,000/. Though the greatest draught of water in the floating harbour (some 20 feet) and the dimensions of the original locks (150 feet long and 36 feet wide) may appear to us at the close of the

nineteenth century somewhat insignificant, they were, no doubt, up to the estimated requirements of that day, and I think we can recognise in Jessop's work the impress of a great mind.

The Cumberland Basin was deepened and improved, and the lock accommodation was increased by Brunel in 1850 by the construction of a lock, 350 feet long and 62 feet wide, and again by Howard in 1871, who made another lock, 350 feet long, 62 feet wide, with 2½ feet of water at high water of neap tides. Thus is the present limitation of the access of shipping to the town docks, and though we realise its insufficiency for modern vessels, we can appreciate the energy of those who have gone before us, and who found the funds for or designed works which have for so many years well fulfilled their purpose.

The approach to Bristol from the sea—that is to say, from King Road in the Bristol Channel—is certainly unpromising for large ships, and indeed, when contemplated at low water, appears not a little forbidding. Something has been done, and more is now in progress, towards straightening, deepening, buoying, and lighting the tortuous course of the Avon below Bristol. More, no doubt, would have been undertaken in former years, if the great rise of tide in the river had not provided, at spring tides, a depth and width for navigation which were sufficient for practical purposes, until the size of modern ships imperatively demanded increased facilities of approach. I think it is a remarkable thing that vessels of 3000 tons burden, 320 feet in length, and drawing 26 feet of water, succeed in reaching Bristol, and that the trade in the heart of the city continues to increase.

Those acquainted with the strong tides of the Avon, or with its bends, which do not exceed in places a radius of 800 feet, and, lastly, with what might be the consequences of a long vessel grounding in a channel which has only a bottom width of 100 feet, cannot but recognise the skill and nerve of the pilots in navigating large vessels from King Road to Bristol. This is done by night as well as by day, and so successfully that the rate of insurance for Bristol is no more than it is for Avonmouth or Portsmouth, the entrances of which are in the Severn, or than for many ports situated on the open sea.

We have similar examples of what can be done by the systematic development of pilotage skill in the Hooghly, the River Plate, the Yangtze Kiang, the Mississippi, and other rivers where special men have been evolved, as it were, by the demand, and navigators with safety of success, which are so full of dangers that they might well appear impracticable. Experience, indeed, shows us that, given a trade and a depth of water rendering access possible, ships will make their way to ports through all kinds of difficulties and with a wonderfully small margin of water under their keels, reminding one of the boast of the Mississippi captain that he could take his steamer wherever the channel was a little damp.

To return, however, to Bristol and the Avon: in spite of all efforts to keep pace with trading requirements, the time arrived, in 1868, for providing improved dock accommodation, which would avoid the navigation of the Avon, and at the same time afford deeper locks and more spacious quays than could be given in Bristol itself. The Avonmouth and Portushead docks accordingly were built between 1868 and 1878, and acquired by the Corporation in 1884. Both are fine works for their period, but even in their case the rapid development of modern shipping has occasioned a demand for enlargements of the facilities which they afford. Accordingly, a matter which is again agitating Bristol is still further dock accommodation, and there has been a sharp contention whether this should be effected by what is implied in the somewhat barbarous word "docking" the Avon, or by new docks at King Road. Docking implies the construction of a weir and locks at Avonmouth, so that the Avon would be impounded and make one sheet of water nearly six miles long to Bristol, the natural discharge of the river being provided for by outfall sluices, while the alternative of docking the Avon is to be found in great additions to the docks either at Avonmouth or Portushead.

In the peaceful atmosphere of Section I, I will not enter upon the various aspects of these antagonistic proposals, and will merely say that I have no doubt that in some way Bristol will keep ahead of what is wanted, and that I wish the city and the engineer who may carry out any of the ideas which may be eventually adopted every success and satisfaction in such important undertakings.

(a) Leaving, then, for the present all local considerations, and seeing that a large part of my own work has lain in the

construction of new docks and in the alteration of old docks, I propose now to say a few words on what appear to me to be at present the salient points on these subjects in relation to the growth and the requirements of our merchant navy.

In the first place one cannot but be struck with the great demands which have come with some suddenness on the present generation for increased dock and quay accommodation. The British people are the chief carriers of the world, and are indeed those "that go down to the sea in ships, and occupy their business in great waters." This can be appreciated when we consider that annually our over sea import registered tonnage is thirty four millions, and our export registered tonnage is thirty eight millions. Our coastwise traffic amounts to sixty three million tons per annum, making together a tonnage to be dealt with of one hundred and thirty-five million tons. If we add to these figures the tonnage of vessels in ballast and the number of calls of those vessels in the coasting trade which touch at several ports in the course of one voyage, we must add a further fifty five millions of tonnage, making a total of one hundred and ninety millions of tonnage using our ports yearly, and if we divide these figures by, say, three hundred days, to provide against more or less idle days, bad weather, and the like, we have the result of six hundred and thirty three thousand tons per diem entering and leaving our ports. If we assume an average ship of three hundred registered tons, which is probably not far wrong, we have about two thousand one hundred trading vessels entering or leaving our ports daily—a flotilla of startling numbers.

In truth, the magnitude of our mercantile navy, as compared with that of other countries, is astonishing. We have ten and a half millions of tons, against a total of thirteen millions of tons belonging to all the other nations of the world, in which are included three millions of tons of steam vessels engaged in the lake and river traffic of the United States. Descending to particulars, our merchant fleet is eleven and a half times that of France, seven times that of Germany, eighteen times that of Russia (in Europe), two and three-quarter times that of the United States (inclusive of the craft on the great lakes), six and three quarter times that of Norway, fourteen times that of Italy, and fourteen times that of Spain. Out of our total tonnage of ten and a half millions, six and three quarter millions are steam vessels, and the proportions in relation to the steam tonnage of the other countries above referred to are approximately the same.

Again, it is instructive to note how small a proportion of the trade of other countries even including coasting traffic, is carried in ships belonging to the country in question. Thus, whereas we as a nation convey in steamships 76 per cent of the aggregate tonnage of our own ports, only the following proportions of the total trade of other nations are carried by the shipping of each country in question —

France	about 30 per cent
Italy	" 19 "
Germany	" 43 "
Russia (in Europe)	" 7 "
Norway	" 56 "
Sweden	" 29 "
Holland	" 26 "
United States (over sea)	" 15 "

Further, it is a recognised fact that a very large part of the balance of the above proportions is conveyed in British ships frequenting the various foreign ports and acting, as I have said, as the ocean carriers of the world.

Thus in the best returns available I find that British shipping conveys the following proportions of the over sea commerce of other countries —

Italy	44 per cent
Germany	38 "
Russia	57 "
Norway	18 "
Sweden	27 "
Holland	27 "
United States	60 "
France	(not given)

The experience of the Suez Canal again tells the same tale, for of the total tonnage passing through that international waterway 66 per cent is British. This is nearly seven times that of the shipping of the next largest contributor, which is Germany, and nine times that of France.

This vast amount of carrying trade is in British hands, because we can do it cheaply as well as efficiently. I believe that the whole of our commercial fleet is worked at a very narrow margin of average profit, though in the aggregate it forms one of the most important factors in our country's position among the nations of the world.

We are often reminded of how greatly the value of our exports exceeds that of our imports, but we should not forget that the profit on the transport of both goes chiefly to the British nation as shipowners, in addition to the profit which is earned by them in the carriage of merchandise from one foreign port to another.

What an important thing it thus is to the prosperity of this country, not merely that our own ports should be convenient and adequate to all demands, but that our ship-builders should be able to keep pace with the demands of this huge transport traffic! We find in this connection that we add about half a million of tons of shipping annually to our register, and that we lose about 250,000 tons annually by wreck and by vessels becoming old or obsolete, so that, as a matter of fact, the average annual increment of our mercantile navy for the past twelve years is about a quarter of a million of tons.

The remarkable development within recent years in the cheapness of steam navigation, the improved methods of building and rigging of sailing ships, and various economic causes have resulted in a large increase of the average size of ship engaged in over sea voyages with a comparative diminution in the number of the crews of each description of vessel. Greater draught of water is consequently demanded, and as a better knowledge of ship building has indicated that the beam of ships can be considerably increased without involving greater resistances, we may expect to see ships to increase not only in length and depth, but also in width.

The largest steamer twenty years ago (excepting of course the *Great Eastern*, which was a magnificent conception, though in advance of her time and its requirements) was, I believe, the *City*, of 5500 tons burden, her length was 488 feet, and her draught and beam were 27 feet and 42 feet respectively. At the present time the *Kaiser Wilhelm der Gross* is 625 feet long, her beam is 66 feet, and her draught is 27 feet, and we know that these dimensions will soon be exceeded.

A modern liner now being built will have a length of 704 feet (or 24 feet longer than the *Great Eastern*) with a beam of 68 feet and a draught of 28½ feet. The great steamers for the transport of cattle are 585 feet long, 64 feet beam, and 30 feet draught and upwards, carrying 14,000 tons of cargo. Some of the large sailing vessels carry over 6000 tons dead weight and draw 28½ feet. Ships of war, though not so long as liners, have a beam of 75 feet with a draught of 31 feet, and though in the commercial marine we need not perhaps anticipate any great further increase of draught of water, the demand for which is largely governed by what is available in foreign ports or rivers and in the Suez canal, the fact that men-of-war can, with due regard to economy of propulsion, be built with great width of beam in proportion to length, seems to indicate that we must be prepared in the future for a considerable increase of beam for cargo-carrying vessels.

We have further to note that, owing, no doubt, to the vast improvements of marine steam engines and boilers realising unlooked for economy in the combustion of coal, steam vessels are supplanting all but the largest class of sailing vessels as carriers of commerce, almost as rapidly as they did forty or fifty years ago in the conveyance of passengers and as ships of war.

In 1897, out of a total shipping trade (cargoes and ballast) dealt with in ships of all nations at the ports of the United Kingdom, amounting to ninety millions of tons, eighty one millions of tons, or 90 per cent, were conveyed by steam vessels; whereas, in 1885, out of a total of sixty four millions of tons, fifty millions of tons, or 78 per cent, were in steamers. If we take, however, the tonnage of cargoes and ballast conveyed to and from her own ports by British ships only, we find that in 1897, out of a total of sixty-four millions of tons, sixty-one millions of tons, or 95 per cent, were in steam vessels; whereas, in 1885, but 85 per cent of the total tonnage conveyed by British vessels was in steamships.

Of the tonnage of vessels built in the United Kingdom in 1885, 50 per cent were steamers, but in 1897 the proportion was 86 per cent; and to sum up, we find that in the commercial fleet of the United Kingdom and British Possessions, as between 1887 and 1897, sailing ships have decreased 16 per

cent. in number and have, in spite of the building of a certain number of exceptionally large vessels, decreased 9 per cent in average size; while steamers have increased 23 per cent in number and 16 per cent. in average size. The total sailing tonnage has decreased in the same period by 24 per cent., and the steam tonnage has increased by 36 per cent.

The problems thus confronting us, as results of the increased size of all descriptions of over-sea steamships, require much consideration from an engineering point of view, and are further puzzling, and will continue to puzzle, our financial authorities, without whose aid the engineer can do but little.

We ask, Where is all this expansion of requirements to stop, and how far are we justified in extending our view of the wants of the future from the contemplation of the conditions of the present and of what has occurred in the past? This is undoubtedly a difficult question, and he would be a bold man who thought that we had reached finality in the size of ships. Bound up with this consideration are not merely matters of first cost of the accommodation to be provided, but also of the annual expenses in working and maintenance, not only of the docks themselves, but in what is perhaps of more importance, viz the preservation of sufficiently deep and wide approaches to them.

Apart from length, depth, and beam, the midship cross section of modern cargo ships has altered completely of late years, and is now nearly as rectangular in shape as a packing case, excepting only that at the bilges the sides and floor are joined by a curve of small radius. The keel has almost disappeared, and bilge keels are often added. The result of these alterations of shape in the ordinary hulls of trading ships is that the sills and sides of many locks and entrances are now unsuited to what is wanted, and consequently their original power of accommodating vessels is most seriously diminished.

Until lately, it was generally considered that locks 600 feet long, 80 feet wide, and 26 feet deep were sufficiently capacious, with some margin for future wants, but I think we must now go further in length and depth, and not improbably to some extent in width. We find that at Liverpool the Dock Board have ordered vestibule basins to act as locks 1150 feet long and 520 feet wide, with entrances 100 feet wide and 32 feet deep, and somewhat similar dimensions were talked of for the entrance lock of the recently proposed Windsor Dock at Pnarth, which was intended to be 1000 feet long, 100 feet wide, and 34 feet deep at neap tides.

Again, apart from the question of locks and entrances, the older docks themselves are beginning to be found too shallow and too narrow for modern vessels. In docks which are deep enough at spring tides and too shallow at neap tides, and which are opened to the "tide of the day," much may be done to improve the depth by systematic pumping, so as to keep the surface always at the level of high water of spring tides. By this expedient, large areas of old docks may be to that extent modernised at the expense, perhaps, of new entrance locks and the annual cost of pumping. This latter yearly outgoing is not an important matter. At Liverpool and Birkenhead 230 acres of nearly obsolete docks have been thus improved at a capital cost of about 66,000*l.* for pumping machinery and an annual expenditure of 6000*l.* I am executing a similar improvement by pumping in one of the smaller docks on the Thames, and contemplate it on a larger scale at an important dock there, and also at Hull.

The conditions of commerce now require also, in order to realise the necessary economy of transport, the greatest despatch, for demurrage on the large and expensive modern steam vessels is a most serious question. Thus there must now be no waiting for spring tides, or, if possible, for rise of tide on the day of arrival. Every steamer expects to discharge her cargo on to the quay without waiting for much stacking, still less for trucks; and under modern conditions dock work must be got through in one-third of the time which was considered proper ten or twelve years ago. From these reasons larger quays and warehouses, better railway approaches, improved sidings, and better machinery are all necessities, as well as deeper water and better approaches.

These demands have come on us, as I have said, not so much gradually as more or less suddenly, and the call for improved docks is general, and, in my opinion, it will be continuing.

Liverpool last year undertook to spend nearly five millions on such works, and we know of very many important projects at other places. Taking the expenditure within the past decade,

and adding to it the authorised expenditure at Liverpool, at the great ports on the Bristol Channel, on the Thames, at Southampton, Hull, Middlesbrough, Hartlepool, Sunderland, the Tyne and its neighbourhood, at Grangemouth, the Fife Ports, at Glasgow, the Ayrshire Ports, the Cumberland and Lancashire Ports, and so round the British coasts to Preston, I roughly estimate an expenditure, either made during the past ten years or contemplated, of from 35 to 40 millions.

These are large figures, and we ask from whence will an adequate revenue come; for it is a more or less accepted fact that docks by themselves do not produce more than a very moderate return on their cost, though, of course, there may be exceptions to every rule. Apart from the expenditure which has been undertaken much remains to be done, and the source of supply of the capital required is a highly important consideration. I venture to think on this point that we should learn to realise that under modern conditions docks should be considered largely in the light of being railway stations for goods and minerals and, in many cases, for passenger traffic. Docks and quays, together with improved approaches from the sea, are, in fact, the means of bringing traffic to the railways (and, to a less degree, to the canals) of a country, and should be looked upon as links in the chain of transport and inter-communication.

They are certainly as necessary adjuncts of a railway, at least in our country and in respect of goods and minerals, as large stations and depots are in all important towns.

The older view of our Parliament was that docks and railways should lie in different hands, but I much question whether this idea should now commend itself. It is difficult, as I have said, for a dock enterprise standing alone to make any considerable return on its cost, and though it is true that capital can be found under guarantees of an already developed trade by some of the great Dock Trusts, such as at Liverpool or Glasgow, the return is but a modest one, and not such as is likely to tempt capitalists to new ventures in constructing or enlarging many of the docks which stand in need of improvements.

On the other hand, a railway company which gets a fairly long lend for the goods to and from a dock can afford to look at the matter of expenditure on docks with some liberality. We have conspicuous examples of great public benefit being afforded at Southampton and at Hull, where the docks have lately passed from the hands of financially weak companies dependent only on dock dues, to the ownership of powerful railway companies. Similarly, several of the north-eastern ports besides Hull—the large docks at Grangemouth, Barry, Penarth, Garston, Fleetwood, and elsewhere—are further examples, amongst others, in which the revenue of railway companies has been spent on dock improvements with a spirit which would be otherwise unattainable. A dock also must necessarily be nowadays almost wholly dependent for its efficient working on the best understanding being maintained with the railway companies for the prompt and adequate provision of land transport, so that in that point of view also the two interests are one and should be recognised as such.

In the consideration of the advisability for concentration of ownership, there remain only the questions of safeguards against unfair treatment of competitive modes of transport, such as canal and road traffic, and provision against any improper results of monopoly of railway access. These, I think, can be provided by Parliamentary enactment, either by insisting on adequate access under proper conditions for all within reach, or, in any case, of inadequate facilities being accorded, by authorising the construction of other docks in the hands of competing railway companies or of other aggrieved parties, with in such cases railway privileges. With these safeguards the public could be efficiently protected, and, if this be so, I cannot but think that, *ceteris paribus*, the trading community will be better served by docks directly connected with railway companies than by separate existences and management. On the one hand, I hope that those who administer the great railway undertakings will realise this community of interest, and, on the other, that Parliament will favour intimate financial relations between docks and railways, instead of more or less systematically discouraging such connection. This question is one which is peculiarly interesting here at Bristol, where the docks are in the hands of the Corporation, and where the railway companies carry the traffic, which, but for the docks, would be largely non-existent.

(3) Leaving now the question of modern docks and shipping,

as to which, as I have said, Bristol is interesting to engineers, there are one or two other matters of history which appeal to Section G in this locality. In the first place, Bristol was the birthplace of the Great Western Railway. I, K. Brunel, its engineer, had previously, by public competition, been selected to span the gorge of Clifton by a suspension bridge of the then almost unrivalled span of 702 feet. Again, under the influence of Brunel, Bristol became the home of the pioneers of Transatlantic steamships, and the story of the initiation of the enterprise is thus told in the memoirs of his life. In 1835, at a small convivial meeting of some of the promoters of the Great Western Railway, some one said, "Our railway to Bristol will be one of the longest in England," and Brunel exclaimed, "Why not make it the longest line of communication in the world by connecting it with New York by a line of steamers?" Out of this grew the Great Western steamship, and the history of the enterprise and of its success is too well known, at least here, to require any allusion to the steps by which it was brought about. Suffice it to say that, in spite of much discouragement, the Great Western—of the then unexampled size of two thousand three hundred gross tons, and with engines of unparalleled power—was launched at Bristol in 1837, and ran successful and regular voyages till 1857, when she was broken up.

In Section G there are many who can appreciate the difficulties of such a new departure as the Great Western steamship, even if they had been confined to the design and study of a vessel and engines of unprecedented size, but it is not easy to realise the anxiety and trouble caused by the dictum of a man of science so universally adrooled as Dr. Lardner, at the meeting of the British Association in this city in 1836, that the whole idea of ocean navigation on voyages as long as from Bristol to New York was at that epoch an abstract impossibility.

In these days of criticism of the past, often involving the rehabilitation of individuals, it is interesting to note that Dr. Lardner's part in condemning beforehand the construction of the Great Western steamship and the ideas on which she was designed has been of late years unduly minimised. It has been said that all Dr. Lardner meant was to express a pious doubt as to the commercial prospects of ocean navigation. I have carefully read the *Proceedings* of the time, and I am brought to the conclusion that his words and writings will admit of no such interpretation. Dr. Lardner's views, arrived at after calculation and reasoning, were precisely expressed and boldly and honestly enunciated by him. The words of the discussion here appear not to have been preserved, but in an elaborate article in a *Quarterly Review* in 1837, which is, I believe, admitted as having been written by Dr. Lardner, he said, "that in proportion as the capacity of a vessel is increased, in the same ratio, or nearly so, must the mechanical power of the engines be enlarged and the consumption of coal augmented." He based his views that success was impossible on principles which he supposed to be sound, but which were, in fact, assumptions—viz. that the resistance to the progress of a ship varied directly with her capacity, that a certain number of tons of coal were required per horse power for the voyage across the Atlantic, and that, this being so, enough fuel could not be carried in a ship, however large she might be made.

Brunel, on the other hand, contended that Dr. Lardner's views were fundamentally erroneous; for that, whereas the capacity of a vessel increased in the ratio of the cube of her dimensions, the resistance to her progress varied more nearly as the square. Thus, by adopting a proper length, beam, and draught, a ship would not only carry coal for the journey to New York, but be commercially successful in respect of cargo and passengers.

It is interesting to note that 9 lbs. of coal per indicated horsepower per hour (as compared with our present 14 to 21 lbs.) was the approximate coal consumption which was more or less accepted by both sides in the controversies of 1836 and 1837.

We know now that the resistances encountered by a ship are not merely dependent on her dimensions, but comprise wave-making at various speeds, bringing form and proportion of dimensions largely into the necessary calculations, but I want to point out that the line of divergence of the different views of Lardner and Brunel was sufficiently precise and quite crucial. It is true that Dr. Lardner, in later criticisms of 1837, retreated somewhat from his position of 1836, introducing more of the commercial aspect of the case and stating that no steam vessel could make profitable voyages across the Atlantic, at

least until marine engines were immensely improved; but, even so, it seems clear that the fundamental matter at issue in 1836 and 1837, the period of Dr. Lardner's active criticism, was the question of the resistances increasing in the same ratio as the capacity. The results of these *est cadaveris* statements by Dr. Lardner about the Great Western, then in process of being built, must have caused great anxiety to the promoters and much preliminary distrust of the ship on the part of the public. They were, unquestionably, honestly arrived at, however much they were due to reasoning on unascertained premises, and this latter is the reason for my venturing now to refer once more to them. As a matter of fact, the ship started from Bristol in 1838, and arrived at New York in fourteen days with 200 tons of coal in her bunkers.

Let me remind you of another somewhat similar instance of the way in which the anxieties of engineers have been unnecessarily increased and public alarm gratuitously, though honestly, aroused. When the designs of the Forth Bridge—of which the nation, and indeed the world, is proud—had been adopted both by the Railway Companies who were to find the capital and by Parliament, a most distinguished man of science—the then Astronomer Royal—came to the conclusion that the engineers had neglected certain laws which he anticipated respecting the resisting power of long struts to buckling, and that the bridge ought not to be constructed, as he considered that, to use his own words, "we may reasonably expect the destruction of the Forth Bridge in a lighter gale than that which destroyed the Tay Bridge." All this was stated no doubt from a strong view of public duty, in a letter to a public newspaper, though sulcosequently and frankly withdrawn. If the laws of his calculations were right, the conclusion might have been correct, but the fact was, that there was no foundation worthy of the name for the reasoning. Again, another distinguished mathematician publicly criticised the Forth Bridge with equal vigour, basing his views that it was fundamentally incorrect on another set of equally erroneous assumptions, maintaining again that it should not be permitted, because he proved by reasoning on those assumptions that it must be absolutely unsafe.

Once more, in ship-building, until Mr. William Froude, some years prior to 1875, made his experiments by means of models on the highly difficult and otherwise almost insoluble causes of the retardation of ships and their behaviour in waves, beginning at the beginning taking nothing for granted, and eliminating all elements of possible errors, little or nothing was known of the laws governing these questions. Laws had been laid down by high authorities as to the causes of retardation of ships, many of which, in fact, were not true, while some of the assigned causes were non-existent and some real causes were unrecognized. Mr. Froude was told that no information could be learnt from experiments on models which would be applicable to full-sized ships, and that ships must continue to be designed and engines built on data which, scientifically speaking, were assumptions. The outcome has been that Mr. Froude's *vis a priori* depreciated experiments, with models have solved most of the questions relating to that branch of naval architecture, and at the present time every ship in the Royal Navy, and not a few in the merchant service, are designed in accordance with the data so gained.

Another example of hasty generalisation occurs to me, and that is on the important question of wind pressure. Tredgold, who undoubtedly was one of the soundest of engineers, laid down in 1840 that a pressure of 40 lbs. per square foot should be provided for, reasoning, no doubt, from the fact that such a pressure had in this country been registered on a wind gauge of a square foot or less in area. As a consequence, he assumed that the same force could be exerted by the wind on areas of any dimensions. Thus roofs and bridges, wherever any calculations of wind pressure were, in fact, made, were designed for a pressure of 40 lbs. per square foot of the whole exposed surface, and under the alarm caused by the fall of the Tay Bridge in 1879, the piers of which were not probably strong enough to resist a horizontal pressure of one-fifth of such an amount, a further general assumption was made, and railway bridges throughout the kingdom were ordered by the Board of Trade in 1880, acting no doubt on expert advice, to be in future designed, and are designed to this day, to resist 56 lbs. of horizontal wind pressure on the whole exposed area with the ordinary factors of safety for the materials employed, as if such horizontal strain were a working load.

It had, for a long time previously to this order of Government being issued, been suspected that these small-gauge experiments were untrustworthy, and subsequent experiments at the Forth

Bridge on two wind gauges of 300 square feet and of 14 square feet respectively, indicated that with an increase of area the unit of pressure fell off in a very marked degree. Under the same conditions of wind and exposure, the larger gauge registered a pressure 38.7 per cent. less per square foot than the smaller gauge. I have been able to carry experiments further at the Tower Bridge by observing the pressure on the surface of the bascules of the bridge as evidenced by the power exerted by the actuating engines. In this case we have a wind gauge of some 5000 feet in area, and it has been shown that, while small anemometers placed on the fixed parts of the bridge adjoining the bascules register from 6 to 9 lbs. per square foot, the wind pressure on the bascules is only from 1 to 1½ lbs. per square foot.

It is difficult to imagine the amount of money which has been expended in unnecessary provision against wind strains of 56 lbs. per square foot on large areas in consequence of this hurried generalisation from insufficient data. I know something of what the provision for 56 lbs. on the square foot for wind cost at the Tower Bridge, and I do not wish to mention it, but if the public had been told that the dictum of experts, arrived at however hastily in 1880, was to be set aside in the construction of that bridge, all confidence would have been beforehand destroyed in it, and I suppose no Committee of Parliament would have passed the Act.

I have mentioned these matters, which could be added to by many similar instances in other branches of applied science, not for the sake of reviving old controversies or of throwing a stone at highly distinguished men, honoured in their lifetime and honoured in their memory, nor for the sake of criticising more modern men of science or a Government Department. Still less do I wish to question the necessity and value of mathematical calculations as applied to the daily work of engineering science, but I recall the circumstances for the purpose of once more pointing out the extreme value of experimental research and of bespeaking the utmost caution against our being tempted to lay down laws based on unascertained data. We know the tendency there has been at all times to generalise and to seek refuge in formulae, and we cannot but know that it is not at an end now. We ought to recognise and remember how few physical questions had been exhaustively examined sixty years ago, and may I say now comparatively few have even now been fundamentally dealt with by experiment under true scientific conditions? The investigation of physical facts under all the various conditions which confront an engineer requires much care, intelligence, time, and last, not least, not a little money. In urging the vital necessity of investigations, I am sure that I shall not be understood as decrying the value of the exact analysis of mathematics, but we must be quite sure that the premises are right before we set to work to reason upon them. We should, then, exert all our influence against rules or calculations based in rely on hypothesis, and not be content with assumptions when facts can be ascertained, even if such ascertainment be laborious and costly. In a word, let us follow sound inductive science, as distinguished from generalisations, for "Great is truth and mighty above all things."

In connection with this subject, I may congratulate the Association generally, and this Section in particular, that there is now more hope for experimental science and some endorsement of research in this country than at any former time. The vital necessity of further work in these directions has long been recognised by men of science and was notably urged by Prof. Oliver Lodge. Last year, in no small degree owing to the exertions of Sir Douglas Galton, K.C.B., who presided over the British Association in 1895, and brought the question very prominently forward in his inaugural address on that occasion, a highly influential deputation waited on the Premier to urge that England should have a Public Physical Laboratory at which facts could be arrived at, constants determined, and instruments standardised. The importance of the questions which could be determined at such an institution in their influence on the trade and prosperity of the country, independently of the advancement of purely scientific knowledge, cannot well be exaggerated.

Our Government, while somewhat limiting the scope of the inquiry, appointed a small Committee to examine and report on this highly important subject. It is no breach of confidence to say that the Committee, after taking much evidence, visiting a similar and highly successful institution on the continent, and studying the question in all its bearings, were convinced of the great public benefits which may be expected from such an

institution, and have unanimously reported in favour of its establishment.

I feel sure that we shall all earnestly hope that Government will carry out the views of the Committee, and I venture to suggest that each of us should use what influence he may have, to induce the Chancellor of the Exchequer to find adequate funds for an institution which may be of the greatest benefit not merely to scientific research, but to the commerce of these islands, threatened as it is on all sides by foreign competition of the most vigorous description—a competition which is supported by every weapon which the science of other lands can forge for use in the struggle. It being acknowledged that our own work in life is to deal with physical facts and apply them for the use of our fellow men, we may have good hopes that at such an institution as I have indicated, directed, as it no doubt will be, by the highest scientific superintendence, we shall be able, at least far better than at present, to have a sound knowledge of many facts which are obscure, and to deal with the many new conditions under which the applied science of the future will have to be carried on.

Those who know most of the problems of nature feel the more strongly how much remains which is unknown and realise how completely those who teach require throughout their lives to be always learners. Let each of us then in our special walk of life, seeking for further enlightenment on the various problems of our work and in the application of that science which we love, humbly recognise that,

"All nature is but art, unknown to thee,
All chance, direction which thou canst not see,
All discord, harmony not understood."

INTERNATIONAL SEA FISHERIES CONGRESS AT DIEPPE

THE movement for the international discussion of matters connected with the sea fishing industry has made such progress during the past few years that a summary of the proceedings of the recent international congress held at Dieppe should interest readers of NATURE, especially as the regulation of the industry tends more and more to be determined in accordance with the evidence accumulated by scientific investigators. The Dieppe Congress was organised by the Société d'Enseignement professionnel et technique des Pêches Maritimes, and is the second international congress promoted by that society. The previous congress was held at Sables-d'Olonne in 1896, on which occasion Mr. (now Sir) John Murray was the British representative. More than 300 delegates assembled at Dieppe, among whom may be mentioned Mr. C. E. Fryer, of the Board of Trade, Dr. J. H. Fullerton, formerly of the Scottish Fishery Board, Mr. Walter Garstang, representing the Marine Biological Association, Mr. O. T. Owen, of Grimsby, Mr. Johnsen, of Hull, Drs. Brunchorst and Bull, of Bergen, Dr. Malm, of Gothenburg, M. Tabary, of Ostend, Prof. Vinciguerra, of Rome, Dr. Valle, of Trieste, Dr. Kishinouye, of Japan, Mr. Thorndike Nurse, of the United States, and of course a large number of French delegates representing the Government and various fishery societies and schools, fishing centres and municipalities, including M. Roché, Inspector General of Fisheries, Prof. Pernier, Baron Jules de Guerne, MM. Lavielle, of Dieppe, Canu, of Boulogne, Odin, of Sables-d'Olonne, Courtes, of Marseilles, and Le Saigneur, of Granville. The proceedings of the Congress opened on the morning of September 2 with an address from the President, Prof. Ed. Pernier, Membre de l'Institut de France. The greater part of the President's address was devoted to an examination of purely French problems—the relative scarcity of steam trawlers and liners, the need of greater solidarity, of a spirit of co-operation and compromise among rival fishing industries, the present unsatisfactory arrangements—or lack of arrangements—for fishery research. Thus, he said, seemed to demand the creation of a central Fishery Board for France, similar to that of Scotland, which should be charged with the duty of coordinating the work of the numerous marine laboratories in which fishery research is now carried on without concerted aim. Proceeding then to matters of more general interest, he pointed out the advantages which would ensue if the study of plankton could be put upon an international basis by a regular organisation of the marine laboratories of different countries, or by international co-operation in deep sea expeditions for the solution of problems

connected with the migrations of fishes. At the same time, he said, it would not do to be too ambitious. The extravagant expectations which were held some years ago as to the beneficial effects of sea-fish hatcheries had not been realised either in America, in Scotland or in Norway. Even if the idea were sound, the actual plan of operation needed modification, since the young fish were being turned into the sea at too early an age. Moreover, he asked, would it not be simpler, and in the end more profitable, to complete the investigation of the whole life history of valuable fishes before launching upon costly and problematic schemes of fish multiplication? To ensure the adequate discussion of these and similar problems, the President, in conclusion, expressed the intention of himself and his colleagues to propose the creation of a permanent international committee for the organisation of future congresses on sea-fisheries, which would extend and complete the work initiated by the French Society.

The subsequent discussions of the congress took place partly at general meetings, partly at the meetings of different sections. Four of the latter were constituted, viz (1) Scientific Researches, (2) Fishery Apparatus, Preparation and Transport, (3) Technical Education, and (4) Fishery Regulations. The subjects which came before the general meetings dealt with oyster and mussel culture, provident institutions (insurance against accidents, &c.), international regulations for preventing collisions at sea, and co-operation amongst fishermen. As regards the sectional meetings, the topics of general interest naturally fell chiefly within the scope of the first and fourth sections. In the first section the following were the more important papers read: (1) On the natural history and fishing grounds of the Tunny in the Gulf of Gascony, by M. Odin, in which the author showed that the migrations of the Tunny of these waters are less extensive than was formerly imagined, since the fish can be taken in the Gulf throughout the year, although the actual fishing grounds shift with the seasons; (2) On the natural history of the mackerel, by Mr. W. Garstang, in which it was maintained that, as a result of researches recently carried out by the Marine Biological Association, the common species of mackerel can be subdivided into several local races, viz an American, an Irish, and a race common to the English Channel and North Sea. These researches lead to the conclusion that the winter haunts of the mackerel cannot be situated far from the localities first visited by the several races in the spring; (3) On a proposed biological and physical investigation of the English Channel during 1899, by Mr. Garstang, in which the author invited the co-operation of French societies and naturalists with the Marine Biological Association for a joint periodic survey of the Channel during the coming year. The proposal was supported by Baron Jules de Guerne and M. Odin, and a resolution on the subject was unanimously adopted; (4) On the sea-fish hatchery at Floddevigen, by Captain Dannevig (read in his absence by Baron de Guerne). This paper gave rise to a vigorous discussion on the efficacy of hatcheries. Captain Dannevig contended that the success of his methods was attested by the statistics of cod taken in Christiansia Fjord, but this statement was categorically denied by Dr. Brunchorst, and also adversely criticised by Dr. Fullerton and M. Canu.

The principal papers read in the fourth section were as follows: (1) On trawling in territorial waters, by M. Sauton, (2) On the necessity of new regulations concerning the mesh of drift and fixed nets, by M. Marraud, (3) Trawling and its effects, by M. Coutant, (4) On the territorial limits, by Mr. Olsen. The discussion which followed these papers was long and interesting, but cannot be fully summarised here. It will suffice, however, to say that at the subsequent general meeting of the congress a resolution against trawling (of all kinds) within three miles from low-water mark was carried by 37 votes to 9, and that other resolutions were carried which would have for effect the prohibition of certain kinds of fishing beyond the present territorial limits, and would prohibit the sale of immature fish, the *minimum* size for each species to be fixed hereafter by an international commission of fishermen, owners, public officials, and scientific experts.

It may be stated in conclusion that the memoirs read before the general meetings of the congress are already published (Paris, Augustin Challamel, Rue Jacob 17), and that the papers communicated to the different sections, with the final resolutions of the congress, will be published in a second volume in the course of the next few months.

NOTES.

We are reminded that the new laboratories of Physiology and Pathology, which University College, Liverpool, owes to the generosity of the Rev S. A. Thompson Yates, will be opened on October 8 by Lord Lister, President of the Royal Society. By his benefaction, Mr. Thompson Yates has strengthened the medical school of the College in a very marked degree, and has enabled the professors of physiology and pathology to take advantage of the most recent additions to our knowledge in their lectures and laboratory instruction. Lord Lister will be accompanied on the occasion by a large and distinguished party. The Lord Mayor will represent the city; Earl Spencer, Chancellor of the Victoria University, has promised to attend and admit Lord Lister to the degree of D.Sc. conferred on him by the Victoria University, Lord Derby, President of the College, will be present, with the authorities of the Victoria University and its Colleges. Among those who have accepted the invitation of the College Council may be mentioned: the Duke of Devonshire, Lord Derby, Lord Spencer, Lord Ripon, Lord Kelvin, Mr. A. J. Balfour, Prof. Michael Foster and Prof. Kucker (the Secretaries of the Royal Society), Prof. Virchow, Sir Douglas Galton, Sir Samuel Wilks, Sir Richard Thorne, the Bishops of Liverpool, Chester, Carlisle, and Ripon, Sir William Gardner, Mr. Justice Kennedy, Sir James Crichton Browne, Dr. Lauder Brunton, Sir Archibald Geikie, Captain Abney, C.B., Sir George King, Mr. Threlton Dyer, Prof. Ramsay, Prof. David Ferner, Dr. Pavy, Mr. R. B. Haldane, Sir John Batty Tuke, Sir Henry Littlejohn, Prof. Schafer, Prof. Burdon Sanderson, Prof. Kathack, Prof. Halliburton, Prof. Meldola, Prof. Poulton, the Dean of Lichfield, Prof. Charlton Bastian, the Hon. Sydney Holland, Prof. Rose Bradford, Prof. Forsyth, Prof. Bower, Dr. Alexander Cox, Prof. Crookshank, Prof. Waller, Prof. Noel Paton, Dr. Ludwig Mond, Dr. Mott, Prof. Stirling, Prof. Lveing, Mr. Gerald Voe, Prof. Macallum, and Dr. Byrom Bramwell. The proceedings will commence with the degree ceremony, which will take place in St. George's Hall at 3 o'clock. Lord Lister will then, with the President, Earl Derby, proceed to open the new laboratories. In the evening a banquet will be given by the Lord Mayor in the City Hall.

ON Sunday, the 11th inst., one of the most destructive hurricanes that has occurred for many years visited Barbados and the Windward Islands, causing immense damage to property and great loss of life. These storms usually occur between July and October, when the equatorial calms are furthest north of the equator, the late A. Poey, of Havana, compiled a list of all hurricanes observed in the West Indies since 1493, and of these nearly 80 per cent. occurred in those months. They usually commence to the eastward, and travel in a north-westerly direction till they reach about latitude 25° N., when they recurve in a north-easterly direction. So far as is known from the meagre reports which have yet been received, this disastrous storm followed the usual track, as the observer of the United States Weather Bureau at Jamaica seems to have forwarded notice through New York that a storm was approaching Barbados from the southward on Saturday, the 10th inst., but, owing to an unfortunate interruption in the cable, the warning arrived too late. The late Rev B. Viñes, S.J., formerly director of Havana Observatory, made a special study of West Indian hurricanes during a period extending over twenty-three years, and shortly before his death (in 1893) prepared a paper upon the subject for the Meteorological Congress at Chicago, which is regarded as the most satisfactory statement of the behaviour of these storms that has yet been made. This paper has just been published in a separate form by the United States Weather Bureau. In it the author discusses very completely the general laws of cyclonic circulation and translation,

including the law of the recurring of the path of the hurricanes in the different months of the cyclonic season

THE Press Association states that on Thursday last Mr. Stanley Spencer and Dr. Berson ascended from the Crystal Palace in a balloon inflated with pure hydrogen gas, and attained the remarkable altitude of 27,500 feet, or only 1500 feet less than Coxwell and Glaisher's highest in 1862. Numerous scientific instruments, including a self-recording aneroid barometer, were carried, and also compressed oxygen for inhaling at the greatest height. The descent was near Romford. At 25,000 feet the air became so rarefied that both explorers had to breathe the compressed oxygen taken with them. The balloon had a capacity of 56,500 cubic feet.

It is reported through Reuter's Agency that a stream of lava from Vesuvius has destroyed a part of the roadway leading from the observatory to the lower station of the funicular railway. A mass of molten rock is flowing down the mountain side in three streams—one along the foot of Monte Somma, a second through the middle of the Vetrana zone, and a third along Monte Crocella. The stream running round the base of Monte Somma continues to burn the chestnut woods, and nearly reaches the observatory. The central flow has reached a point close to the Carabinieri barracks, while the Crocella stream, after passing close to Messrs Cook and Son's building, has reached the northern edge of the Canteroni ridge, whence it may also threaten the observatory. News from Naples on Saturday states that the eruption is becoming hourly more active and more menacing, and the streams of molten lava are spreading in every direction. The most threatening is that which is flowing down the immense valley of Vedrina, which is now almost filled. The observatory, which was originally situated at a height of 610 metres, is now said to have sunk over 27 metres owing to the sinking of the ground. Seven new craters have formed round the central crater, without, however, in any way diminishing the activity of the latter. The gravity with which the outbreak is regarded is chiefly based on the fact that the volcano is throwing out stones and scoria similar to those ejected in the great eruption of April 1872, when the lava streams covered an area of two square miles, averaging 13 feet in depth, and the damage to property exceeded three million francs.

THE Berlin Academy of Science has made the following grants for botanical work—2000 marks to Prof. Eichler, for the continuation of his work on East African plants, 600 marks to Prof. Grisebner for the continuation of his work on German plants, 500 marks to Dr. Loewner, for the completion of his monograph of the Aquifoliaceae.

TWO Walker prizes, of the value of sixty dollars and fifty dollars respectively, are annually offered by the Boston Society of Natural History for the best memoirs written in the English language on subjects proposed by a committee appointed by the Council. The subjects for 1899 are: (1) Is there fundamental difference between "equation division" and "reduction division" in the division of cells? (2) The phenomena and laws of hybridisation. The subjects for 1900 are: (1) Stratigraphy and correlation of the sedimentary formations of any part of New England. (2) A study in paleozoic stratigraphy and correlation. Memoirs must be sent in on or before April 1 of the year for which the prize is offered.

THE Mayor of Angers has appointed M. Albert Gaillard curator of the Lloyd herbarium in that town.

WE learn, from the *Botanical Gazette*, that Dr. A. Möller, of Eberswald, has undertaken the preparation of a memoir of Fritz Müller, so well known in connection with the flora of Brazil, and with problems connected with the pollination of plants.

THE death is announced of Dr. H. Trimble, professor of practical chemistry, Philadelphia College of Pharmacy, and editor of the *American Journal of Pharmacy*.

NEWS has been received that Mr. de Windt, the geologist with the Belgian scientific expedition for the exploration of the Congo, was drowned on Lake Tanganyika on August 9, with Mr. Karsley, a gold prospector.

THE *Pall Mall Gazette* announces that Mr. S. A. Rosenthal and Dr. S. J. von Komocki have succeeded in preparing matches which do not contain yellow phosphorus, and are capable of ignition by friction upon any surface. It is claimed that these matches can be manufactured as cheaply as the ordinary ones.

SIR W. MARTIN CONWAY has sent to the *Daily Chronicle* the news that on September 9 he reached the top of Yllimani, a peak of the Cordilleras which rises behind the town of La Paz, at a height of 22,500 feet above sea level. With Sir Martin Conway are the two Swiss guides, Antoine Manguiez and Louis Pellissier, who last year were in Alaska with the Duke of the Abruzzi, and made the ascent of Mount St. Elias. The party took five days to reach the top of Yllimani from the highest point of cultivation.

MRS. HUBBARD has sent us the following translation of a passage from the "Niva," recording an interesting observation. "The naturalist, Ostrovomov, director of the biological station at Sevastopol, last summer made some excursions along the coast of the Crimea. One morning, the sea being at the time calm and clear and the sky blue, he observed whole clouds of small creatures, like moths, fluttering above the smooth surface of the sea. Ostrovomov, with his son and a boy from the station, observed that each of these small creatures rested for a while on the surface of the water, as though gathering strength, then made a spring and flew high in the air, and plunged again into the sea. They captured some of these, and examined them under the microscope, and what was Ostrovomov's astonishment on discovering that these flying creatures were the soft-shelled crablike *Entomostraca*, belonging to the family *Pontellina mediterranea*."

THE world's record for high kite flight was (says *Science*) broken on August 26 at Mr. Rutch's observatory by Messrs Clayton and Ferguson, who despatched a tandem of kites into the air until the highest one reached an altitude of 12,124 feet above the sea level, a height 277 feet greater than any kite had previously reached. Five miles of line, weighing 75 pounds, was let out, while the weight of the kites, recording instruments and secondary line, was 37 pounds, making a total of 112 pounds lifted into the air. The recording instrument was made by Mr. Ferguson and was of aluminum, weighing three pounds, and registering temperature, pressure, humidity and wind velocity. The ascent was begun at 11 o'clock, and the highest point reached at 4.15 p.m. The kites passed through clouds when about a mile above the surface of the earth, but while above the clouds the instruments showed the air to be very dry. At the highest point the temperature had fallen to 38°, and the wind velocity was 32 miles an hour. At the ground at the same time the temperature was 75° and the wind velocity 32 miles. The highest wind velocity recorded was 40 miles an hour at a height of 11,000 feet. The wind on the ground at this time was from the west, while at the highest point reached by the kites it was south-west. The flight was one of a series of high ascents made during the spring and summer, averaging about a mile and a half, while on several occasions a height of over 10,000 feet has been obtained.

THE results of meteorological observations made at Rousdon Observatory, South Devon, under the superintendence of Sir Cuthbert Peek, have been published. Interest in local meteorology is necessarily limited, but there are several sections of the present report which appeal to meteorologists generally. The usual comparison was made of daily forecasts issued by the Meteorological Office for the district in which the Observatory is situated with actual weather experienced. The wind and weather predictions were both correct in 85 per cent of the forecasts. The forecasts of wind alone were correct in 90 per cent., and 92 per cent of the weather predictions were fulfilled. The percentage of correct weather forecasts has not been below 92 for the past five years. Sir Cuthbert Peek has made a further comparison of the records of the Robinson cup anemometer and the pressure-tube anemometer. It has been assumed that the factor of the cup anemometer does not depend upon, or vary with, the velocity of the wind. To roughly test this conclusion, a comparison was made of the daily total mileages of wind passing over the Observatory, as recorded by the two instruments, during three periods of about twenty-four days each, when light airs, winds of moderate force, and strong winds, respectively, prevailed. These results show quite clearly the effect of the inertia of the cups in low velocities, the excess of the cup record over that of the pressure tube being as much as 53 per cent., when the mean hourly velocity is as low as four miles. With a moderate wind of eleven miles per hour, however, the cups yield 3 per cent less than the pressure tube, and with a wind of double that velocity the difference is increased to 8 per cent. It is pointed out that these results are based on too few observations to be accepted as final, but they are suggestive, and a fuller comparison on the lines indicated may at some future time be carried out. The factor 2.2 appears, however, to be practically correct for all winds, except when the force is extremely low.

THE two Cantor Lectures delivered before the Society of Arts by Dr D. Morris, C.M.G., on sources of commercial india-rubber, have been published in a pamphlet form. In his lectures, Dr Morris confined himself to describing the rubber plants now existing in various parts of the tropics, their geographical distribution, the conditions under which they grow, and the prospects they afford of being able to meet the increasing demand for rubber. At the outset he made a comparison between india rubber and gutta-percha. It is very well known that india rubber and gutta-percha are closely allied substances, not only in their origin but also in their chemical composition. They are both obtained from the latex of certain plants, and are composed wholly of carbon and hydrogen. But, as Dr Morris points out, the similarity ends here. The most conspicuous property of gutta-percha is that of becoming soft and plastic on immersion in hot water, retaining any shape then given to it on cooling, when it becomes hard and rigid. Caoutchouc, on the other hand, does not soften in moderate heat, is impervious to water, alcohol, most acids, and gases, and retains for a long period its original elasticity and strength. Again, gutta-percha is obtained only from large trees belonging to one family of plants, the *Sapotaceae*, confined to one small portion of the world's surface. Caoutchouc, on the other hand, is obtained from numerous families of plants, and these are distributed over almost every part of the tropical regions; they may be low herbaceous plants, shrubby climbers, small trees, or majestic giants of the forest, 150 to 180 feet high. Dr Morris's lectures deal with these plants with special reference to the rubber industries connected with our Colonial and Indian possessions; they are, therefore, of great interest at the present time.

In the *Bulletin International* of the Imperial Academy of Science of Bohemia, Herr Franz Švec discusses the ciliated

Infusoria of the Unterpocermitz Teich, on the banks of which a biological station has been established. Sixty-nine species of Infusoria have been observed, of which ten are new; these are *Holophyra atra*, *Enchelys variabilis*, *Larymaria phialina*, *Pyrodon nucleatus*, *Lamontus lanceolatus*, *Lacophyllum axilli*, *Dileptus elephantinus*, *Zoothamnium limneticum*, *Epistylis rotans*, *Rhabdostyla discostyla*.

THE "Communications from the Physical Laboratory at the University of Leiden," published in English under the direction of Prof. Kamerlingh Onnes, afford a striking instance of the activity of foreign Universities in the matter of research. Part 41 contains a paper by Dr E. van Everdingen, jun., on the Hall effect in electrolytes. The author has calculated the amount of the effect in liquids, and has compared the results with those afforded by experiments, but it appears that the observed galvanometric differences of potential in liquids differ considerably (sometimes even in sign) from those which would be caused by the Hall phenomenon. For the present, it therefore appears that we cannot use the phenomenon in electrolytes to obtain a better insight into the nature of the electric current in metals.

THE *Proceedings* of the Royal Society of Queensland (vol. xii.), just published, comprise several papers of interest. In a useful presidential address, Mr C. J. Pound shows how the stockowner is indebted to the microscope, and explains that "all those marvellous and brilliant discoveries relating to the origin, nature, prevention, and treatment of bacterial diseases of our domesticated animals have been mainly brought about by the investigations of such brilliant epoch-making men as Pasteur, Koch, and Lister, whose names will ever be associated with the microscope, and remain as lasting monuments to the science of preventive medicine."—Mr Walter E. Roth contributes some notes on social and individual nomenclature among certain north Queensland aboriginals, personally studied by him. Mr Roth points out that the whole question of class-systems, whereby a relationship, such as it is, is established between aboriginals living miles and miles apart, yet may be mutually unknown personally, has an important practical bearing which has hitherto been apparently overlooked. In the mind of the red North-west Central Queensland savage, all white men are believed to be similarly related, he looks upon any one European as being the brother, brother in law, father, or mother's brother, &c., of any other.—Mr Thomas P. Lucas gives descriptions of Queensland lepidoptera, and Mr Rowland Illidge contributes a list of butterflies of the Brisbane district.

A BRIEF statement of the results of an investigation into the distribution and ethnography of leprosy in the Far East is given by Mr Sydney B. J. Skerchly in the volume of *Proceedings* referred to in the foregoing note. The area embraced in an inquiry carried out by Mr Skerchly and Dr J. Cantlie, extends from the Malay Peninsula, through China, the whole of the East Indian Archipelago, Japan, and the Philippines and the islands of the Pacific; and a large amount of most valuable information as to the distribution of the disease has been obtained. As the area investigated contained every variety of surface, it was easy to determine whether physical configuration was a determining cause of leprosy. The conclusion arrived at is that neither physiographical climate nor geological conditions have any influence upon the distribution of leprosy. Contrary to the general statements, leprosy is not rife throughout the length and breadth of China, entire provinces being free from the disease. An examination of the state of affairs in the Pacific leads to the important conclusion that from the Chinese provinces of Kwantung and Fokien, leprosy spreads with diminishing intensity in all directions, and has formed a new focus in Hawaii of unparalleled virulence. Viewing the facts

from an anthropological standpoint, it appears that so far from the black races being the most leprous, and the yellow the least, over the great area dealt with, the black races are quite free from leprosy, except where, as in Fyl, it has been recently introduced; and the yellow race, the Chinese, is the leper and the distributor of leprosy. In not a single instance are the native races attacked without there being Chinese lepers in the country. In other words, leprosy follows the lines of Chinese emigration, and in the East Indian Archipelago and Oceania is co-terminous and co-existent, in time and area, with the Chinese coolie. Mr Skerchly believes that the only way to stop the spread of leprosy is to put an end to the coolie traffic from the infected provinces, and this cannot be done except by concerted action of the Governments holding possessions in the Far East.

THE WILDE lecture "On the Physical Basis of Psychical Events," delivered by Prof. Michael Foster before the Manchester Literary and Philosophical Society last March, is printed in *Manchester Memoirs*, vol. xli (1898), No. 12.

A COPY of "Bourne's Handy Assurance Manual" (1898), edited by Mr William Schooling, has been received. The volume shows the position of every assurance office, and should be consulted before taking out a policy in any company. Students of statistics will also find the tables useful.

A NINTH edition of Skerchly's "Geology," revised in accordance with the latest requirements of the Science and Art Department's syllabus, has been prepared by Dr J. Monckman, and published by Mr. Thomas Murly. A new section dealing with minerals and their microscopic characteristics has been added, but the general appearance of the book and the illustrations are behind the times.

THE additions to the Zoological Society's Gardens during the past week include a Ring tailed Coati (*Nasua rufa*) from South America, presented by Mr. S. C. Rogers; two Little Armadillos (*Dasypus minutus*) from Patagonia, a Vesperugo Sea Eagle (*Haliaeetus vocifer*), a Chameleon (*Chamaeleo vulgaris*) from Africa, deposited; a Pleasant Antelope (*Tragelaphus oryx*), bred in Amsterdam, purchased; a Crested Porcupine (*Hystrix cristata*), three Swinhoe's Pheasants (*Euplocamus swinhoei*), three Mandarin Ducks (*Aix galericulata*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE NEBULA OF ANDROMEDA.—A telegram from the Centralstelle, Kiel, received here on the 20th, announces that Strupphoff has observed a stellar like condensation near the centre of the nebula of Andromeda.

This is not the first time that variations near the centre of this nebula have been observed. In 1885 a star of 6.5 mag. appeared suddenly near the centre, giving a continuous spectrum containing probably a few bright lines, in 1886 this had entirely disappeared. Espin thought that the nucleus was variable, and that he could see stars in it; and Young, with a 23 inch refractor, confirmed this. The fine series of photographs taken by Roberts also indicate that the nucleus of the nebula is variable.

An examination of the nebula on the early morning of the 21st, with the 30-inch reflector of the Solar Physics Observatory, South Kensington, gave the idea that the centre of the nucleus seemed more elongated and was more of a stellar nature than usual. The application of the spectroscope indicated nothing more than a continuous spectrum, although there may have been faint bright lines which could not be seen.

COMETS TEMPEL 1866 AND PERRINE-CHOPARDET.—Just after we had gone to press last week we received another telegram, concerning the comet discovered by Pechuelo, saying that it was Wolf's comet and not that of Tempel.

NO. 1508, VOL. 58]

Another telegram, dated September 15, informs us that Perrine, on September 13, discovered a comet at 16h 14m. Local Mean Time, in position of R.A. 9h 41m 40s and Declination +30° 36'. Two circulars from Kiel (Nos. 11 and 12), which have since reached us, give the elements of the comet's orbit and an ephemeris for the present month, besides telling us that Chofardet made the same discovery independently at Besançon on September 14, 16h. 37m local time.

Both the elements calculated by Berberich from observations on September 12, 13, 15, and by Perrine and Aitken from observations on September 13, 14 and 15 are very similar, so we will confine ourselves to the former, which are namely —

T = 1898 October 19 9565 Berlin M.T.

$\omega = 165^{\circ} 56' 29''$

$\Omega = 36^{\circ} 20' 85''$

$i = 29^{\circ} 16' 41''$

$\log q = 9.57608$

For the present month the positions of the comet for every two days are as follows —

1898	12h R.A.	Decl.	Br
Sept 22	10 35 2	+25 9 9	
" 24	10 48 3	23 32 4	2 08
" 26	11 1 11	21 46 6	
" 28	11 14 23	+19 52 3	2 67

CATALOGUE OF NEBULAE.—Mr Lewis Swift publishes in a recent number of *Astr. Nachr.* (No. 3517) a catalogue of nebulae which have been discovered by him during the last three years. All the observations were made at the Lowell Observatory, namely +34° 20', enabling him to search further south than when he was situated at Rochester, New York. He says "I am further south than any observatory in Europe and America north of the equator except the one at Tacubaya, Mexico, yet I find that the southern sky has been pretty thoroughly explored by Sir John Herschel, Dunlop, and others."

The present catalogue contains 243 objects, some of which are very interesting. Thus, Nos. 6 and 27 are described as being very singular. They resemble a fairly bright double star, each component being an exceedingly small nebulous disc "like an imaginary double nebulous Uranus distant about 5" or 6".

No. 56 is described as "a nebulous hair-line of one uniform size from end to end," while No. 91 has one side extending like a brush.

In addition to the above, this keen-eyed observer has discovered no less than four comets, one of which is of short period, and his son has discovered a fifth, also of short period.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE Calendar of University College, Bristol, for the Session 1898-99 has been published. The College offers excellent opportunities for the study of science, languages, history and literature, and possesses good facilities for giving systematic instruction in the branches of applied science more nearly connected with the arts and manufactures. Medical education is provided by the Faculty of Medicine of the College, and students can complete in Bristol the entire course of study required for the various medical and surgical degrees.

In order to encourage systematic study, a definite course of instruction extending over three years has been established in the Morley Memorial College (for working men and women), Waterloo Bridge Road. In the first and second years all students will follow almost the same course of study, but in the third year they will take up a selected group of literary, mathematical, or scientific subjects. Organised courses of this kind are of far greater educational value than the study of a large number of disconnected subjects.

MAJOR P. G. CRANKIE's annual report to the Board of Agriculture on the distribution of grants for agricultural education and research in 1897-98, has just been issued as a Parliamentary paper. The total amount distributed during the financial year to each of the fifteen institutions receiving assistance was 7200*l.*, as compared with 7000*l.* in the previous year. The following table shows how this money was expended. —

Institutions aided	Work.	Grant, 1897-98
University College of North Wales, Bangor	Collegiate centre	£ 800
University College of North Wales, Bangor	College farm	300
Durham College of Science, New Castle on Tyne	Collegiate centre	800
Durham College of Science, New Castle on Tyne	College farm	300
University College of Wales, Aberystwyth	Collegiate centre	800
Reading College	Collegiate centre	800
Yorkshire College, Leeds	Collegiate centre	600
University College, Nottingham	Collegiate centre	600
South Eastern Agricultural College, Wye	Collegiate centre	600
Cambridge and Counties Agricultural Education Committee	Collegiate centre	500
Eastern Counties Dairy Institute, Ipswich	Dairy instruction	300
British Dairy Institute, Reading	Dairy instruction	300
Royal Botanic Garden, Edinburgh	Clinic for foresters and gardeners	150
Bath and West Southern Counties Society	Field experiments	50
Bath and West Southern Counties Society	Cider experiments	50
Bath and West Southern Counties Society	Cheese and cheese research	300
Highland and Agricultural Society	Agricultural experiments	100
Aberdeen Agricultural Research Association	Agricultural experiments	100
Stewartry of Kirkcubright Dairy Association	Cheese discoloration inquiry	50

The grants to the collegiate centres in England and Wales are of a general character, intended to assist and improve the local provision made for instruction in the higher forms of agricultural education. The thirty-two separate counties are thus provided with an efficient and economical means of systematising their local instruction, and of supervising demonstration plots and agricultural experiments by securing scientific advice and the assistance of qualified lecturers drawn from the collegiate educational staffs. The Durham College of Science and the University College of North Wales have been granted special assistance in consideration of their having taken farms for practical work and field experiments.

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, September 12.—M. Faye in the chair.—Meadow land in warm dry summers, by M. Ad Chatin. A list of those species of plants which have been found to be the most capable of resisting a hot, dry summer.—Observation of an aurora borealis, by M. H. Deslandres. An aurora was observed at Meudon on September 9 about 9 p.m., and its general direction was very nearly that of the magnetic meridian, the rays having a greenish colour.—On the crystallisation of the anhydrous sulphides of calcium and strontium, by M. Mourlot. The crystallised sulphides of these metals can be prepared in two ways, either by heating a mixture of the corresponding sulphate with carbon, or by simply fusing the anhydrous sulphate obtained by the method of M. Sabatier, the temperature employed being that of the electric furnace with a current of 3000 amperes at 60 volts. The crystallised sulphides thus produced are more stable than the corresponding amorphous salts, and are attacked with difficulty by reagents, carbon at a very high temperature converts them into carbides. Both crystallise in the cubic system, and are without action upon polarised light.—On a double carbide of iron and tungsten, by M. Percy Williams. This compound, the existence of which was indicated in an earlier paper, is prepared by heating a mixture of tungstic acid, iron and coke, in the electric furnace with a current of 900 amperes at 45 volts. The ingot formed in the reaction contains the carbide of tungsten WC, probably W_2C , and the double carbide $3W_2C \cdot 2FeC$.—On the commercial extraction of thorium, by MM Wyronhoff and A. Verneuil. The mineral is worked up by one of the usual methods as far as the production of the oxalates, these precipitated by sodium carbonate and hydroxide, and the washed precipitate dissolved in hydrochloric acid. This liquid is treated with small portions of barium peroxide, until hydrogen peroxide no longer gives a precipitate. The deposit, which is

of a reddish orange colour owing to the presence of cerium, contains the whole of the thorium, with about 20 to 30 per cent. of impurities. Further treatment with hydrogen peroxide after a similar set of operations readily gives a very pure thorium. The method has been applied on the large scale, starting with five tons of monazite, with good results.—On the composition of the humic constituents of the soil, by M. G. André.—On the transformation of luminous variations into mobile relief, by M. Dussaud.—On a new coccus, by M. Louis Leger. The new species is found in the digestive tube of *Lithobius hesolus*, and belongs to the genus *Echinospira*. Its microgametes are furnished with vitelline cells, the name *E. vitellacea* is suggested.—Influence of light on the form and structure of the branches of the wild grape and ground ivy, by M. Maige. Comparative cultures placed in light of decreasing intensities showed that both from the morphological and anatomical points of view, a feeble light increases the adaptive powers of climbing plants, diffused light favouring the conversion of a flower bearing bud into a tendril. Direct sunlight produces the opposite effect.—On the adherence of the cupule solutions used for curing the cryptogamous diseases of the vine, by MM Guillon and Gouraud.

THURSDAY, SEPTEMBER 29, 1898

THE RETURN FROM IDEALISM

The Metaphysic of Experience By Shadworth H Hodgson 4 vols. Pp. xix + 459, viii + 403, viii + 146; viii + 503. (London Longmans, Green, and Co., 1898.)

DR. SHADWORTH HODGSON'S first essay in metaphysic was made a generation ago, and his well-known "Philosophy of Reflection" dates from twenty years back. In the interval his work has undergone review and development, revealed from time to time in his presidential addresses in Albemarle Street, but it is in the present volumes only that the mature results of his courage and patience appear in their due perspective. It is a matter for general congratulation that so original a thinker should have been able to put forth his system in such relative completeness.

Neither empiricism which treats unanalysed concretes as ultimate, nor materialism and idealism which lay the stress on the facts of some one order only which we have somehow and in some sense come to know, can offer us an adequate explanation of the world as it exists for common-sense. Materialism fails to explain consciousness because matter is known for what it is only in terms of consciousness. Idealism fails to solve the problems of the material world as known to science because it hypostatizes thought, imputes real agency to it. Nor is the compromise which makes the material and the conscious simply diverse aspects of the same reality less vicious in its use of unproven assumptions. There is but one way left—experimentalism or the interrogation of consciousness by the analysis of its process-contents. Such analysis is what Dr Hodgson calls metaphysic, and upon it may be built a constructive and complementary philosophy with unverifiable results. The analysis and construction together constitute philosophy as a whole.

If it is possible to reach to what is in any sense of the words beyond, and independent on, consciousness, it can only be so by making distinctions in the analysis of the contents of consciousness itself. Dr Hodgson's first book and volume then is devoted to this analysis. What exactly do we find in consciousness? If we dismiss the prejudices due to system and incident to language, we have yet to face the fact that the analysis can only be taken in hand when one has long built up his common-sense world, and the conditions of past consciousness cannot fail to affect present. Dr Hodgson's device to reach consciousness in its lowest terms is to introduce new facts into consciousness, a note, say, and then another struck on an unseen piano, and abstracting from our knowledge of their names, significance, and associations, to inquire what is present in the empirical moment of perception. He finds two distinguishable elements involved, time and feeling. The first note is felt to have receded, though retained in consciousness, as the second is struck. Further consideration shows that time must be taken as having duration and as continuous, and that even the first note must begin to recede from the point at which it begins to be felt. Thus all perception is

retrospective or reflective. This fact is important as leading us at a later stage to contrast the reflective functioning of consciousness as a knowing with its forward movement as existent, to apprehend, as we compare retention with reintegration, the significance of the phrase "below the threshold of consciousness" familiar to the physiological psychologist, to learn without surprise that there is in antithesis to consciousness an order of real conditioning, in which the neuro-cerebral system is proximate condition of consciousness as its conditionate and evidence.

But for the present Dr Hodgson riots in pure analysis—how we become aware of time future, how we distinguish objective thoughts and objects thought of, "what" and "that," nature and genesis, essence and existence, how and in what proportions tactual and visual perceptions give us our knowledge of that preeminently "common sensible," space, how the external world and the localisation of consciousness in our bodies become known, and the like. Particularly significant is the part played by desire and disappointed expectation in leading us to distinguish the phantasmagoria of objective thoughts from the order of objects thought of as really existing.

In actual achievement as well as in fruitfulness of suggestion this analysis is a veritable triumph. Its central thought is that the agent and subject is the organism, and not any immaterial Psyche or transcendental ego implied in consciousness. The interruptions of continuity in consciousness, and the part therefore assignable to the brain and other nervous system in the explanation of memory, lead us, if we can render matter, in some sense indifferent to consciousness, intelligible as a real existent, to a theory in which it is held that in and from the cognitive order we can infer to an order of real conditioning of which consciousness is the dependent concomitant. The point on which the critic who is not prepared to deny Dr Hodgson's other main positions would be most likely to take issue is the Lockean doctrine, that percept-matter and physical matter are so related that matter is known as it actually is. Here, perhaps, the antithesis of noumenon and phenomenon might find rehabilitation.

The order of real conditioning is the field of the positive sciences, except psychology. This deals with consciousness as an existent in dependence on its proximate conditions in the neuro-cerebral organisation.

Book II deals with the positive sciences and contains admirable analysis of some of their fundamental conceptions. In this section Dr Hodgson disclaims expertise, and supports himself on authorities, but his treatment of the ultimates of mathematics and physics is wholly admirable. Corresponding to his treatment of space in Book I, which was of quite palmary merit, comes an adverse criticism of the claims of non-Euclidean space-theories. His discussion of the Newtonian conception of matter leaves nothing to be desired. In chemistry he tends to follow "the new chemistry", in the biological sciences, though interesting, he is discursive and too little "positive" to be convincing.

With Book III we pass to the science of practice and practical science, to the analysis of conscious action, logical, poetic or æsthetic, and ethical. And here the

analysis of volition, and the demonstration of the continuity of reasoning in logic and ethic are substantial contributions to speculation. It is probably in the sphere of practice and in especial in ethic and religion that Dr. Hodgson finds the true task of consciousness as something other than the fly upon the wheel of real conditioning. At any rate the denial of efficiency to consciousness and the attribution of real activity to the organism as such, to the conscious being and not to his consciousness, has not emptied morality of content. Conscience and personality have their meanings, and very full and rich ones in the new system. Conscience as self-consciousness in selective attention is no doubt wholly conditioned by the neuro-cerebral system, but it is the sole criterion of morality, its preferences are perforce imperatives, its judgments as to the anticipated effect of actions upon character are final in scorn of consequence. No system of prudence will satisfy Dr. Hodgson, but only a moral responsibility for character which requires free-will.

His treatment of this well-worn topic is somewhat unconvincing. Inward determination or self-determinism is freedom, and in this sense even the inorganic is partially free, and in each higher organisation of matter such freedom is intensified. And we are not to think that laws of nature "compel", there is no necessity in the order of real conditioning.

So far, so good. But is this enough? The *de facto* presence of real alternatives in the order of real conditioning is what is required to justify responsibility on Dr. Hodgson's theory, and he will not allow himself to make fallacious inferences from sense of effort and so forth. Does he not tacitly rest the case on the belief that otherwise pleasure and pain, desire and volition, the whole contents of consciousness as such are illusion and inutilty? In acknowledging only "apparent design" in nature, and resolving the teleological into the aesthetic judgment, he precludes himself from this escape. The influence of Kant's later critiques is all the more obvious from Dr. Hodgson's antagonism to the earlier.

Out of the moral consciousness arises the religious. And of this Dr. Hodgson is at pains to show the competence and limits.

The fourth book on "The Real Universe" is really a *Religionophilosophie*. Approached in a characteristically analytical way. Matter or adverse occupancy of space by coherence of parts is composite even in its minima. It must therefore have been produced by non-material real conditions. Either this or the "aseity" not yet proven of matter. It is upon these unseen realities, which through matter their product work in the organism and condition consciousness, that faith fastens. Upon them it projects, in a way satisfying only to the practical reason, those conclusions which religion derives from ethic and completes ethic by. Among other vaticinations in this field consciousness stumbles pathetically upon a theory of an organism formed by the neuro-cerebral system with the growth of character, an organism perchance disengageable at death and capable of a future life with those it has loved and lost—the theory of the authors of "The Unseen Universe." But Dr. Hodgson is severe with himself and will not take any surmise for metaphysical truth.

The strength or the weakness of the system lies in the refusal to attribute agency to consciousness. Where, if it does nothing, and the neurosis all, lies the use of consciousness? and yet if we introduce final causes, what becomes of Dr. Hodgson's system? Or is its sole use the speculatively unjustifiable self-projection into the unseen which characterises the ethico-religious consciousness?

But beyond the significance of any single doctrine of "The Metaphysic of Experience," or even of its central doctrine, is that of its method. Many of its results must hold good, but, were it otherwise, the book would live, because of the unflinching sincerity which is its keynote. H W D

AN INTRODUCTION TO GEOLOGICAL SCIENCE

Geology for Beginners By W. W. Watts, M.A., F.G.S.
Pp xvii + 352 (London Macmillan and Co., Ltd., 1898)

THE progress of science demands from time to time new text books by fresh workers, and in the handy little volume before us we have presented to us the leading facts and principles of geology concisely explained and well illustrated by the light of the most recent researches. The author himself, one of the most energetic of observers and teachers, and with a varied experience both in the field and laboratory, has made excellent use of his opportunity, and in this "Geology for Beginners" he has given to the earnest student one of the best introductions to the science ever published. There are other works on elementary geology which will prove more fascinating to general readers, who seek to become acquainted only with the principles of the science, but those who desire to master the subject must enter into details, and they will do well to follow step by step the instructions given by our author.

From the study of a few selected examples of rock at home, he leads us to the study of rocks and rock-structures out-of-doors. We are then taught to observe the wear and tear of rocks by various agencies, and to understand the formation of gravels, sands, and clays, including in course of time the mode of origin of crush-conglomerates. The action of compressed air on sea-coasts, and many other little matters, not usually explained in text-books, are introduced to our notice. In all information relating to mineralogy and petrology, to metamorphism and earth-movements, the author's statements are clear, and as full as need be for an elementary student. Each chapter is divided into paragraphs with bold headings, and at the end there is a recapitulation which is followed by a series of questions. The author has planned his work on the revised syllabus of the Science and Art Department, and the questions which he quotes are those which have been set by that Department and by the Oxford and Cambridge Schools' Examination Board.

Throughout the volume the subjects are illustrated by diagrams, by photographs of hand-specimens and microscopic slides of rocks, and by photographs of natural exposures of rocks. In the chapters relating to the successive geological periods there are numerous figures of fossils. In most cases the names of the genera only are

given, but in some instances the names of the characteristic species are also mentioned. This portion of the work would, we think, bear amplification in a new edition. We note that *Eozoön* is abandoned as a fossil. The Archaean system is regarded as Eozoic, as the bands of limestone and graphite which it contains are probably of organic origin, while among the Longmynd rocks "obscure traces referred to worm-tracks and trilobites have been found."

Concluding chapters deal with the origin of landscape, with escarpments, base levels, &c., and there is a brief outline of economic geology. Too little attention is perhaps, as a rule, given to this last professional aspect of geology, but in his introduction the author rightly observes

"Pursuing these studies we are brought into contact with constituents of the earth's crust which are of value in the arts and manufactures, and it is our business to learn about them, where they are found, and how they were formed, and if possible to point out where similar things may be found elsewhere."

Applied geology must of course be based on the firm footing of science—on a foundation the main features of which are so ably delineated in the present little volume.

OUR BOOK SHELF

Plant Life, considered with special reference to Form and Function. By Charles Reid Barnes, Professor of Plant Physiology in the University of Chicago. 1p vii + 428 (New York: Henry Holt and Co., 1898).

IT is rather difficult to speak with justice about Prof Barnes' little book. The idea, set forth in his preface, of attempting to give a general and somewhat philosophical account of plant life such as shall be useful to young readers, is an ambitious one, and the author has, here and there, almost realised parts of it. But we must confess that, taken as a whole, the book is not satisfactory—it is more provocative of yawning and somnolence than keen interest. At times, too, it is amazingly behind the times. The discredited figures of centosomes are reproduced with a fidelity worthy of a better cause, and the account given of the ascent of sap is worse than misleading. Some of the figures, too, are very bad, and it is difficult to see the use of a delineation of a *Fucus* egg, such as presented in Fig. 42.

The physiological part is in some respects, perhaps, less open to objection than much of the rest of the volume, but here also there is a deal of useless talking round points, giving wordy definitions instead of definite ideas. What is the good of telling young students that irritability is the power of responding to a stimulus, without giving them some idea of what a stimulus itself consists of? Quite enough knowledge of chemistry is presupposed in the earlier chapters to have warranted a more precise explanation of the nature of a stimulus than "the external change which brings about the reaction", and the metaphor of the trigger and loaded gun ought to be carefully explained, if it is to be put before young readers.

These are a few of the defects which mar the execution of a task perhaps almost impossible of fulfilment within the compass of a small book, but if the author has not, at least in our judgment, succeeded in writing a book pre-eminently useful for students, it may, as a kind of note-book, prove of service to young teachers. The volume ends with tolerably good appendices containing directions for laboratory work and the collecting of suitable material for study.

Stories of Starland. By Mary Proctor. Pp 186 (New York: Potter and Putnam Co. London: G. W. Bacon and Co., Ltd.).

TO write a book in a conversational style for the instruction of children requires a deal of art and close familiarity with the curious workings of young minds. Books of this kind have usually to be classed as failures, and the present volume only rises in parts above their level. In the first place, few of the illustrations will interest children, and the figures of Mars on p. 69, and of the Orion Nebula on p. 157, are in no way satisfactory. Then the children's questions and answers are too ready and apt for an average child to follow or retain in his mind. Thus, on the four pages 20-23, Master Harry, who plays the part of the inquiring boy, has impressed upon him that it would take a train nearly one hundred and seventy-five years to get to the sun, that at the rate of two cents a mile the fare would be nearly two million dollars, that walking at the rate of four miles an hour for ten hours a day the journey would occupy more than six thousand years, that a cannon ball would take nine years to reach the sun, and the sound of the explosion fourteen years, and that if an imaginary long arm touched the sun, the pain of burning would not be felt for one hundred and fifty years on account of the time taken in the transmission of sensation through nerves.

Now all this may be very well in a popular lecture in a country village, for grown-up people sometimes like to be impressed by statistics of the millions upon millions type, but it has no educational value whatever, and is entirely out of place in a volume intended for the instruction of children. In fact, Miss Proctor makes the common mistake of crowding too many uninteresting details into her book, and of describing too many appearances which her pupils will be unable to see for themselves.

By far the best part of the volume is that in which the chief constellations are described, and the legends connected with the constellation figures are related. These star stories from the mythology and folk-lore of different peoples are better suited to the mental condition of a child than the descriptions of petty details concerning planetary motions and appearances.

A number of short poems of variable quality are interspersed through the pages, and may help to relieve the narrative when children of poetic temperament are the readers or listeners.

Canalisations Electriques. By R. V. Picou. Pp 172. (Paris: Gauthier Villars, Masson et C^{ie}).

DETAILS concerning the erection and working of aerial lines for electric currents are given in this volume, which belongs to the well-known Aide-Memoire series. The first part of the volume includes descriptions of the wires used, the various forms of insulators, and different kinds of posts and supports used to carry the wires. The second part is concerned with the mounting of lines, all the details as to earths, tension, and protection against electrical and other disturbances being dealt with. In the third part of the volume the chief formulae and tables used by electrical engineers engaged in wiring work are brought together.

Contributions à l'Etude de l'Hérédité et des Principes de la Formation des Races. By J. M. Harracu. 1p 172. (Paris: Félix Alcan).

HERE and there in this little volume the reader will find an interesting point referring to facts or views bearing upon heredity, but the search for this material for thought in a waste of words is very wearying. The author writes with apparent conviction that he has new things to say, and he certainly does express some ideas which appear to merit consideration, so that students of heredity may find it worth their while to glance through the volume.

LETTERS TO THE EDITOR

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

Flow of Water

BEING away from home at this place, I did not see a copy of NATURE of September 15 in time to reply in the next issue to the letter of Prof Osborne Reynolds. That letter is to a great extent a discussion of a point of considerable interest, viz the clear border visible in my experiments with air injected into flowing water.

The discussion is, however, preceded by a statement which, whether intentionally or not, seems to imply that not only had Prof Reynolds previously with similar apparatus made most of the experiments I have published during the last year or two, but had communicated to me his methods and shown me this apparatus. Apparently, therefore, my humble part has been the production of a certain number of photographs of effects slightly modified from those dealt with by him.

Now, though questions of this sort are of little interest, I have no alternative but to reply to all this, because, unfortunately, the real facts of the case as to my indebtedness to Prof Reynolds have left quite a contrary impression on my mind to that which might otherwise be supposed.

With brevity in view, I will merely refer your readers to an article in NATURE (May 12), which gives a brief outline of my research up to that date. In that article is mentioned and duly acknowledged the only point for which I am indebted to the writings of Prof Reynolds, viz the idea of the two manners of motion of water, so ably worked out by him in the *Philosophical Transactions* of the Royal Society.

Beyond this I cannot recall a single idea, communicated verbally or otherwise, which I owe to Prof Reynolds, and I certainly have never seen or heard of any other appliances which bear the remotest resemblance to those I have designed and used.

If the foregoing simple statement of fact is not sufficient, I am quite prepared to enter into the subject more in detail, although I should regret to have to do so.

My reply to the other portion of the letter will be rendered much more clear by means of diagrams, and I will therefore defer my answer to it until I return to work at Liverpool.

The Movement of Encke's Comet

In Prof Poincaré's paper on the "Stability of the Solar System," the statement is made that "astronomers have only been able to explain the movement of Encke's comet by supposing the existence of a resisting medium."

It may be of interest if I state that in a paper published in the *Astronomical Journal* for January 1896, I have shown that the movement of Encke's comet may be explained by the application of well-known physical laws, which have been verified experimentally by a number of physicists, and that no supposititious resisting mediums are necessary. It is also of interest to note that the same phenomena which explain this change of rate also explain the other cometary phenomena, such as the formation of cometary tails, the curious bridge in Biela's comet, and enable us to predict that comets are unstable bodies and must ultimately split up into swarms of meteorites, the fragments continuously separating from each other.

I might also call attention to the fact that since, according to this theory (which has so far accounted for all the facts known without assuming any premises except well-known properties of matter), a comet can be used as a gigantic absolute electrometer (its tail being the index) for measuring the electrostatic potential of the sun and planets, accurate observation of the curvature and spectra of comets' tails are much to be desired throughout their whole period of visibility.

NO. 1509, VOL. 58]

A Request for Zoological Literature.

I WISH to ask my fellow zoologists, especially those on the continents of Europe and America, to be kind enough to send me, for our library here, separate copies of their papers and memoirs on zoological subjects. Here, in New Zealand, a naturalist is not only isolated, but has no efficient supply of current zoological literature; the nearest library containing modern periodicals being Sydney—a week's journey. The museum library in Dunedin, though well equipped in some respects (travels and older books), is extremely poorly provided with periodical literature. We take in the English journals and *Proceedings of Societies*, &c., but we do not purchase a single German periodical (with the exception of the *Naples Mittheilungen* and the *Jahresberichte*), and only one French journal, *Annales des Sciences naturelles*.

Hence, we are fearfully handicapped in our research work, and in our efforts to keep abreast of zoological advances. Out of sight, here, is to be out of mind to a great extent, and I would earnestly ask my colleagues in Europe and America, in their kindness, to help to remedy this disadvantage. Even if we wish to purchase a work in Europe, it takes at the very least three months before we can obtain any reply to our orders, and more usually four or five months intervene.

You dwellers in and near cities and large libraries cannot appreciate this great inconvenience.

Dunedin, New Zealand, August 14

Stereochemistry and Vitalism.

WHEN listening to Prof Japp's stimulating presidential address, I could not but wish that he had pursued his subject further and inquired into the antecedents of the life made carbon compounds.

These are probably formed in the first place, not as compounds of only C, H, and O, but rather as constituents of a large molecule which has nitrogen as its centre. The growth of the C, H, and O groups depends on the lability of N compounds, &c.; their proneness to transfer matter and energy. If, then, the formation of the said carbon compounds is controlled by the nitrogen, whose atoms (with a valency alternating between 3 and 5) are asymmetrical or have a symmetry different from that of the carbon atoms, does this peculiarity of the nitrogen determine the asymmetry of the resulting carbon compounds?

A White, or Milky Sea.

I LEFT Bombay for England in January 1881, on board the P and O s.s. *Sumatra* (Captain Briscoe), and on February 1, the vessel being then in N lat 14° and E long 53° (not far from the position described by your correspondent) had an opportunity of witnessing the phenomenon known as the "Milky Sea," rarely seen except in these waters. The following extract from my book, "An Engineer's Holiday," describing and explaining the appearance, may interest Mr Barrett.

"The whole ocean, from the ship to the visible horizon, looked as if it were covered with snow, whose surface evidently shone by the reflected light of the sky, for Venus, being very bright, threw a distinguishable line of radiance across it, while the phosphorescent crests of waves were now and then seen breaking above the layer of shining matter which overlaid the water."

"A current, always encountered north of Socotra, set the ship, on the day in question, fourteen miles to the northward of her course. This stream was crowded with large medusae, visible not only during the day, but also at night, when, being themselves non-luminous, they appeared as whirling black discs in the general phosphorescence of the ship's wake. The ship's officers fully believed that this current brings with it, besides jelly fish, enormous quantities of decayed and phosphorescent matter, to whose presence they attributed the appearance of the 'Milky Sea.'"

"The fact, however, that the seeming snow reflects light, and is broken through by quite small waves, disposes of this explanation, and we soon convinced ourselves that the phenomenon is really due to a thin layer of mist lying on the water, exactly

resembling one of those local fogs which every one has seen, and which may give to a valley or even a slight depression the appearance of being snowed up. It occurs when the sea is colder than the atmosphere, and the latter still and heavily loaded with aqueous vapour. Under these circumstances, a layer of air immediately in contact with the water is chilled below the dew point and becomes misty, while that above remains transparent. The upper surface of such a fog, which is only a few inches thick, being seen by the reflected light of the sky" ("An Engineer's Holiday," vol. II p. 314).

The temperature of the sea on the night in question was 70° F., while that of the air was 79°, an unusual amount of difference in the Arabian sea. Water, brought on deck by a bucket, showed no signs of milkiness, though crowded as usual with various phosphorescent organisms. DAN PINCKOY.
The Long House, Leatherhead, September 24

Luminous Clouds?

I OBSERVED a phenomenon at the Lizard, on the night of September 10, which is new to me, but what I presume is meant by luminous clouds.

At 10.48 p.m. several others and myself saw a large patch of what looked like luminous mist suddenly appear just to the south of the aquellation Perseus. It only lasted a very short time, but quickly reappeared accompanied by another which extended from near the extremity of the first to the higher part of Cassiopeia. The longer axes of these patches were in one line nearly east and west, and low down in the west in this line produced, appeared and reappeared a similar patch. Shortly afterwards a similar patch appeared with its longer axis on the same line almost at the zenith. The line of direction of these clouds formed a small angle with the Milky Way. I may state that the sky was quite clear except for a bank low down in the north, and that the light of these clouds was sufficient to attract attention although one was not looking in their direction, and although they were so high in the sky. Several fugitive patches appeared in the west at short intervals, and at 0.10 a.m. (11th) a very bright patch was to be seen in the north-east just afterwards the patch in the west reappeared, and with one or two short interruptions, and, at first, considerable variation of intensity, remained until close on 1 a.m. The position remained, as far as I could see, constant, and at about 0.30 a.m. I fixed its position by means of a flag staff and the top of a wall, and on the following day I took the bearings by the theodolite. The lower edge of the cloud was nearly straight and horizontal, and the angles are for the centre of this lower edge. They are as follows: N 281° 12' E (mag.), elevation 7° 18'.

I thought that if any one is collecting information on the subject, a report from the extreme south and west might be useful, especially as I was able to get the bearing pretty accurately.

I may add that the aurora of the evening of the 9th was well observed throughout Cornwall, though I do not know that I can give much information that would be of value with respect to it.

ARTHUR P. JENKIN

Trewigle, Redruth, September 13

"Crannoges" in Estuaries

I FIND IN NATURE of September 15 a notice of certain remains near Dumbarton as the only known specimens of "crannoges" in tidal water.

The farm-house of Cranry, in the townland of the same name, parish of Inver, County Donegal, Ireland, is supposed to stand on an artificial island in a tidal estuary, that of the Eany, or Eighneach (meaning Ivy) River. The mound is now surrounded by a masonry reivement.

Opposite it, on the right bank of the same estuary, is a low mound which seems artificial, and lower down the old church of St. Natalis stands on another.

I have nothing to propound, but the ground may be worth examining. I have known it for many years, and think all three "crannoges." There is some printed record, not now before me, of the discovery of wooden framework on the right bank of the Eany, in Glebe land. W. F. SINCLAIR.
Chelsea, September 16.

Transference of Heat in Cooled Metal.

Lorsque je vous ai écrit le 30 Juin dernier pour vous prier d'appeler, dans votre estimable journal, l'attention sur un phénomène de conduction de chaleur dans une barre; je pensais parler d'un phénomène bien connu aussi que je le disais dans ma lettre. Je désirais simplement provoquer de la part de quelques uns de vos lecteurs, soit des recherches, soit des enquêtes analogues à celle que j'avais fait de mon côté auprès des artisans et ouvriers; mais je n'avais nullement la prétention de signaler un phénomène nouveau. Le premier physicien qui en ait parlé est à ma connaissance M. Izarn, professeur de physique au lycée de Clermont-Ferrand (France), et qui est connu par bien d'autres travaux. Voyant qu'on a l'air de m'attribuer la découverte de ce phénomène, je vous serais très reconnaissant si vous vouliez bien démentir les lecteurs de votre journal et remettre les choses au point. HENRI BOURGET.
Observatoire de Toulouse, Septembre 13

Horn-feeding Larvæ.

READING the correspondence in NATURE on larvæ in ante-lope horns, reminded me of an experience in India. I was on a shooting trip near the Mt. Pass in May, and brought a sheep for food from a native. Within five minutes of it being killed its horns were removed from the head, and it was found that they contained each some dozen maggots, white, and about half an inch in length. The horns had not been perceptibly perforated, and seemed quite sound. This fact may be well known, but I give it for what it is worth.

G. G. TRAHERNE

"Purple Patches."

IN NATURE of November 12, 1896, there appeared a letter asking for some explanation of certain purple patches frequently noticed by the writer (A. P. Dider) on roadways and pavements, especially at Bath. There were but three replies, two of which suggested "copying ink" pencils as responsible.

The following notes, made recently in Derbyshire by myself, seem so nearly to fit the case that I venture to think a cause, such as here described, or one closely allied, might explain some at any rate, of the cases mentioned. Here are the verbatim notes—

"29/8/98.—At Axe Edge last Wednesday I noticed on a coal pit ventilating shaft (Hatch Marsh Colliery) on the moor certain deepish blue masses on a ledge near the base. Some masses brighter blue, others nearly black. Under a lens appeared to contain horny parts of larvæ and many small seeds. They are probably the droppings of birds. They leave a bluish stain on the stone.

"To day I noticed the same on some pieces of stone on the road to Goyt's Bridge, a steep, rocky road.

"30/8/98.—Visited Axe Edge shaft again. There were no fresh deposits on it. This may be due to almost continuous rain the last four days, but the stains are still there. Also found deposit on one of two stones round shaft and on a piece of wooden staging. They were very plentiful, especially on the tops of the six posts of this staging, where one would expect birds to settle chiefly. The colour and stains were just the same—some reddish purple and some bluish purple. The colour is thus evidently due only to the excreta (?), and not to the body on which deposited. The seeds appear reddish, and it seems likely that the colour is due to them (bilberries are plentiful on the surrounding moor).

"1/9/98.—The seeds are identical with bilberry, and on extracting the excreta with cold water a charred colour is obtained, which leaves a greenish blue stain on paper."

Dulwich

F. SOUTHERDEN

Re-Blossoming of Horse-Chestnut.

THERE is at present (September 20) a tree in South-End, Hampstead, showing a bush of fresh green leaves and a well-formed spike of flowers. Some years back (1893, I think), another tree, in the same plantation, put forth leaves and blossom in September.

J. J. W.

INTERNATIONAL CONFERENCES AND THE BRITISH ASSOCIATION.

THE circumstances under which the International Conference on Terrestrial Magnetism and Atmospheric Electricity met at Bristol, and its relations to the British Association, were fully described in the address of the President which we have already published. The success of the Conference leads to the hope that similar arrangements may be made in future with regard to other international reunions which may be held in this country.

The number of such gatherings is increasing, but, useful as they undoubtedly are, they make serious inroads on the summer vacation, they diminish the few short weeks which, when the necessary holiday has been taken, can be devoted either to research or to preparation for the work of the next session; and lastly they necessarily compete with, and injuriously affect, each other.

Thus it is unquestionable that the fact that physiologists foregathered in Cambridge shortly before the meeting of the British Association was one of the causes why at Bristol physiologists were conspicuous by their absence. Last year the number of British geologists who visited Canada was relatively small, as they could not be in the Caucasus and on the shores of the Pacific at the same time.

It may be impossible to prevent such meetings from interfering when they are held in different countries and when two nations are the hosts, but everything that is possible should be done to prevent it when the gatherings take place in the same summer and in the same country. Steps have recently been taken in this direction. Conferences of zoologists and physiologists were held simultaneously in Cambridge, and the Conference on Terrestrial Magnetism was affiliated to the British Association. This latter plan could not be adopted if the number of persons attending an International Conference was so large that, if the Conference were held simultaneously with the meeting of the Association, it would overtax the receptive capacity of a great town. Such cases are comparatively rare, and in others the aid of the Association is so valuable, that it may be hoped that the precedent now set will be followed frequently.

The conditions of a successful International Conference are interesting and important questions to discuss, an adequate attendance of British and foreign scientific men, and well arranged opportunities for social intercourse. Taking the first two for granted, and dealing therefore only with the last, it is well known that an elaborate scheme of entertainments and excursions is most generously and even lavishly provided by the locality in which the British Association meets. These were, and probably always would be, thrown open to members of an International Conference meeting together with and recognised by the Association. If the number of those attending the Conference was sufficiently large to justify the wish to have some special entertainments—it may be a dinner or an excursion—reserved for them alone, this could no doubt be arranged at a cost to the promoters of the Conference much less than that involved in the holding of an independent meeting. The British Association thus possesses ready-made machinery for the reception and entertainment of foreigners, which would have to be created anew for each independent Conference. On the other hand, no small part of the elaborate preparations for the meeting of the Association is now too often devoted to the entertainment of persons whose interest in science is little more than a hardy annual which blossoms in August or September, and requires a stimulating treatment of cheap excursions to bring it to maturity. No harm would be done to the Association, and good would result in many ways if these were in

part replaced by distinguished foreign visitors and their English *conféres*. The authorities of the Association have shown a praiseworthy readiness to vary their arrangements so as to grapple with new conditions. Though nominally a department of Section A, and working most harmoniously with the officers of that Section, the International Magnetic Conference was practically at liberty to manage its own affairs, and was in no way hampered by red-tape. The Permanent Committee, appointed not by the Association, but by the International Meteorological Conference at Paris in 1896, was added *en bloc* to the Committee of Section A, and was allowed unfettered control of the Magnetic Department of that Section.

If the authorities of the Association are thus wisely liberal in future, there is no reason why at least the smaller International Conferences which take place in this country should not meet in alliance with the British Association.

If a Section can for one year coexist with an almost independent department, there is no reason why similar temporary arrangements should not be adopted on a more extensive scale, should occasion so require. The promoters of the Conference would be saved a great deal of trouble and even of expense. The cost to the Association and to the locality would be no greater than it is now. The persons entertained would be genuine scientific workers. The meetings of the Association would gain in interest and prestige, while at most of the places where the Association meets there would be no difficulty in providing space for several additional Sections if such subdivision were necessary.

The experiment which has been tried this year on a small scale was a complete success, and it is desirable that those who may have the management of International Congresses in future should be fully aware of the readiness which the Council of the British Association has displayed to make the great organisation which it controls as useful as possible. They have much to give, and on this occasion they gave it freely; while, on the other hand, the Association gained both in the interest of its proceedings, and in the usefulness to science which is the object of its existence.

NOTES.

THE seventeenth Congress of the Sanitary Institute was opened at Birmingham on Tuesday, and will continue in session during the remainder of this week. On Tuesday afternoon Sir Joseph Fayrer, Bart., the President of the Congress, delivered an address, in which he surveyed the progress of preventive medicine during recent times, and in the evening the Lord Mayor opened a great exhibition of appliances, machinery, food products, and the like, which is the usual feature of the Congress, and lasts a month. On Wednesday municipal representatives, medical officers of health, sanitary engineers, sanitary inspectors, and ladies held conferences and discussed papers. Thursday and Friday are to be devoted to sectional work, and there are two important lectures, one to the Congress, and one to the general public. Among the topics to be discussed are the relations of medical officers to vaccinal legislation, the milk supply, water analysis, bacteria and infectious disease, hygiene in dress, and the decrease in the birth rate.

THE death is announced at Paris of M. Gabriel de Mortillet, the eminent anthropologist.

THE annual exhibition of the Royal Photographic Society was inaugurated by a *soirée* held on Saturday last, September 24.

At the meeting of the Entomological Society of London, on October 5, a paper by Mr. F. Merrifield, "On colouring of pupae of *P. machaon* and *P. napi* caused by exposing the pupating

larve to coloured surroundings," will be read; and also one by Mr. G. H. Verrall, "On Syrphidae collected near Aden by Colonel J. W. Yerbury."

RECENT researches by Surgeon-Major Ronald Ross have shown that the mosquito may be the host of parasites of the type of that which causes human malaria. Ross has distinctly proved that malaria can be acquired by the bite of a mosquito, and the results of his observations have a direct bearing on the propagation of the disease in man. Dr. P. Manson describes the investigations in a paper in the *British Medical Journal*, and sums them up as follows.—The observations tend to the conclusion that the malaria parasite is for the most part a parasite of insects; that it is only an accidental and occasional visitor to man; that not all mosquitos are capable of subserving it, that particular species of malaria parasites demand particular species of mosquitos, that in this circumstance we have at least a partial explanation of the apparent vagaries of the distribution of the varieties of malaria. When the whole story has been completed, as it surely will be at no distant date, in virtue of the new knowledge thus acquired, we shall be able to indicate a prophylaxis for malaria of a practical character, and one which may enable the European to live in climates now rendered deadly by this pest.

A VALUABLE report upon the various attempts which have been made to bring China grass (obtained from *Boehmeria nivea*) and Ramie or Rhea (obtained from *B. tenacissima*) into use for manufacturing purposes is contained in the *Kew Bulletin* for September. The report describes machines which have been devised to deal with the grass, and indicates the merits and defects of the most important of them. It will be seen from the following summary of the Kew report that the problem has not yet been satisfactorily solved.—"Notwithstanding all the expenditure of mechanical skill and inventive ability, the conclusion cannot be evaded that we are still as far off as ever from being able to place upon the market a finished product which will effectually compete with silk, flax, and the better qualities of cotton. The plants can be grown with the greatest ease. But when the problem of treatment is solved, the supply of the raw material will be limited to warm countries. The cultivation of China grass in temperate regions will never be able to compete successfully with that of Ramie (or perhaps of China grass) in the tropics. It is known that when ribbons can be produced sufficiently cheaply, these can be degummed and turned into flanne as a small cost. The whole question then still turns, as in 1888, on the production of ribbons. We are still waiting for a decorticator which will not merely turn out ribbons fit for further manufacturing processes—that has been accomplished—but will turn out, say, half a ton a day at a small cost. Till this has been found, the planter cannot profitably deal with his crop, and the degumming processes now almost entirely dependent on hand-cleaned fibre from China are paralysed for want of a supply which will allow the finished product to compete with other fibres."

News has been received by the *Times* that the *Antarctic*, with the Swedish Arctic Expedition under Dr. A. G. Nathorst, has returned to Tromsø, after a successful cruise to the seas and islands around Spitsbergen; and the following notes on the results of the expedition are published.—The *Antarctic* left Tromsø on June 8, and proceeded to Bear Island, which was reached on the 11th; a week was spent there. The whole island was surveyed, and a map on the scale of 1:50,000 was drawn by Lieut. Kjellström and Dr. Hamberg. After surveying and mapping Bell Sound, on the west of Spitsbergen, and visiting some points of interest in Ice Sound, the expedition proceeded westwards, and did some hydrographical work as far as the margin of the Greenland ice-pack (78° 1' N. lat., 4° 9' W. long.). The ship was then turned to the south and east of

Spitsbergen, and reached King Charles Land, which was completely mapped on the scale of 1:100,000 and surveyed. From there the *Antarctic* proceeded to White Island, which was circumnavigated; the expedition landed at the only two places where landing is possible, and the geology of the island was ascertained. This island is completely covered by an ice cap, which is broken off at the sea shore, ending in a perpendicular ice-wall, just as is found on the Antarctic Continent, though in miniature. Great table formed icebergs are given off from this ice-sheet. From White Island, which is larger than indicated on the maps, the *Antarctic* made its way through alternating heavy ice and open water to Charles VII Island, whence the expedition proceeded northwards and reached 81° 14' N. lat. The expedition then passed north of the Seven Islands and proceeded to Treuenberg Bay, Grey Hook, and Danes Island, from which they steered southwards along the western coast of Spitsbergen. When the *Antarctic* reached the south end of Prince Charles Foreland the circumnavigation of the whole of Spitsbergen, with the surrounding islands, was completed. The scientific work of the expedition has been most successful; they have brought back large geological, botanical, and zoological collections. The geology, botany, and zoology of King Charles Land are now completely known, and there are evident important connections between the geology of Spitsbergen and that of Franz Josef Land.

THERE are a great number of curious superstitions as to the time of day when a dying person is most likely to draw his last breath, and the tide, the moon, and the wind have all been supposed to have some share in the matter. According to the *British Medical Journal*, Raseni, who has analysed 25,474 cases of death, and 36,515 of birth, where the exact time of day was noted, finds that the maximum number of deaths occur in the early afternoon (2-7 p.m.), and the minimum in the last hours before midnight, while the maximum number of births occur in the early hours of the morning, and the minimum in the early hours of the afternoon. As regards the cause of this, he points out that the hours of the maximum number of deaths are precisely those when the pulse rate and temperature are at their highest in health, and when there is a febrile exacerbation in illness.

THE Report of the Chief of the United States Weather Bureau upon meteorological observations made during the year 1896-97 has just been received. It consists of a volume containing more than four hundred pages, with nearly one hundred large charts and plates. The very valuable work carried on by the Weather Bureau is too well known to meteorologists to need commendation here. The vote for the service during the fiscal year 1896-97 was \$83,772 dollars, but, remembering how very considerably the work has extended during the past few years, we are surprised to learn that this grant is 109,748 dollars less than that made in 1883. In the past fifteen years the number of voluntary observers has increased from 300 to about 3000, and the number of stations on the sea-coasts and the Great Lakes, where storm warnings are displayed for the benefit of mariners, has increased from 41 to 253. These storm warnings have proved of very great service. At each of the 253 stations where the signals are displayed, telegraphic messages, giving the situation, intensity and probable movement of the storm are distributed to the masters of vessels within an hour after the information has been dictated by the forecast official at headquarters. It is estimated by shipowners that one hurricane sweeping the Atlantic seaboard would cause damage to floating craft of more than 600,000. During the past three years ten or more of these destructive storms have visited the coast line of the United States, but in every case the danger warnings were displayed long in advance of the storm, and no marine disasters

of importance occurred. These facts alone justify the appeal of the Chief of the Weather Bureau for an increased grant. His estimate of the money needed to meet the legitimate requests of the agricultural, marine, commercial, and manufacturing interests of the States is 1,044,050 dollars, being an increase of 160,348 dollars. The present report furnishes abundant evidence that whatever money is voted will be used in making the Bureau of service to the people of the States, and of assistance to the progress of meteorological science. In addition to the usual report upon the administrative work, the volume contains an account of the climatology of the year, and papers upon the rainfall of the United States and the floods of the Mississippi Valley, both of which have already been noticed in NATURE.

THE September number of *Annalen der Hydrographie und maritimen Meteorologie* contains two papers of more than usual interest: (1) Yearly isotherms and isobnormals of sea surface temperature, by Dr W. Koppen. The author has calculated the yearly isotherms from the best available sources, including those of the Deutsche Seewarte and the Meteorological Office, and in addition to the usual methods of showing simply the warm and cold currents, he has indicated the districts where the surface water is more than 2° C. above or below the temperature due to geographical position. (2) Contribution to the knowledge of wind conditions on the sailing routes between the equator and Cape Horn, by Dr H. König. The data used are principally those collected for the sailing directions issued by the Seewarte. In addition to various tables showing the distribution of wind directions for months and seasons, and referring to different districts, the author has shown graphically for each month and each 5° square the percentages of the three most prevalent wind directions, with numbers showing their mean force, the calms, and the total number of observations from which the results are deduced. Both the above discussions are accompanied by interesting explanatory remarks.

TELEPHONIC communication has been established between a number of farms in Australia by means of wire fences. The *Australian Agriculturist* publishes a note from a correspondent writing from a station near Cobar, stating that it was easy to converse with friends at a station eight miles distant with instruments connected on the wire fences, and the same kind of communication was established over a distance of thirteen miles. A large number of stations are connected in this way, and the system if widely adopted will do much to relieve the monotony of back country life.

PROF. ZICKLER, of Brunn, has (says the *Electrical Review*) conducted an elaborate series of experiments, which show that a telegraphic instrument can be actuated at considerable distances by a beam of ultra-violet light. He employs a powerful arc lamp as his transmitter, using a screen of glass to produce intermittent flashes of the ultra-violet beam, which embody themselves as dot and dash signals on his receiver. The receiver is an air gap in a circuit containing an induction coil regulated to an electromotive force just below the sparking point at the air-gap. As Hertz long ago has shown, a beam of ultra-violet light falling on the cathode of a strained air-gap, near its breaking-down point, will immediately provoke a discharge. Zickler started by producing this effect over a distance of 2 m. Then, by improving the shape and material of his electrodes and enclosing them in a chamber of compressed air, he was able to increase this distance to 200 m. This is a remarkable result, and it is extremely interesting to physicists to learn that the short and easily absorbed ultra-violet light can influence a spark discharge at so great a distance.

THE attention of several physicists has been of late turned to determinations of the thermal conductivity of rocks. A large number of experimental results, chiefly statistical, and obtained

by using the "Wall method," are detailed by Messrs. B. O. Pierce and R. W. Willson in the *Proceedings of the American Academy of Arts and Sciences*; while Dr Francesco Morano has been engaged in determining the internal and external conductivity of the rocks of the Roman Campagna and the corresponding fluctuations of temperature of the soil (*Atti dei Lincei*, vi.) While these experiments lead to purely numerical results, Dr. Lees, of Manchester, in a paper read before the British Association, has succeeded in establishing the fact that pressure produces a marked increase of conductivity in the less closely-grained rocks, especially sandstone.

THE disposal of the town refuse of Naples has led to a lengthy discussion at the meetings of the Reale Istituto d'Incoraggiamento di Napoli, and the publication of a number of papers in their large annual volume of *Atti*. The subject is introduced by Prof. Paolo Boubée, who seems to rather favour treatment by the Arnold Le Blanc system, or the use of destructors, though it would appear that the refuse of the Neapolitan streets is too wet, and also too poor in carbon, to burn without the additional consumption of coal. At present the street sweepings are taken and deposited some distance outside the city, and the accumulations ultimately used as manure; but the effluvia arising from so large a mass of putrefying matter have become prejudicial to health. It is suggested that the problem might be best solved by a series of experiments on the different alternative methods of disposal; and even the clumsy and wasteful plan of dumping the refuse at sea seems considered deserving of a trial.

AN "Improved form of Hydrometer" by means of which the effect of capillarity is eliminated, is proposed by the Rev. H. O'Toole of Blackrock College, writing in the *Scientific Proceedings of the Royal Dublin Society*. It is similar in principle to Nicholson's hydrometer, but, instead of one bulb, it has two connected by a narrow stem of the same material and sectional area as that which supports the weight. It is first loaded till the lower bulb is immersed, and then loaded till both bulbs are immersed. The additional weights put in at the second observation represent exactly the weight of a quantity of liquid equal in volume to the upper bulb between the two points of immersion.

"A CONTRIBUTION to the Study of Individual Variation in the Wings of Lepidoptera" is given by Mr William L. W. Field in the *Proceedings of the American Academy of Arts and Sciences*, xxxiii. 21. The paper gives the results of an attempt to find in a particular species answers to the following questions: (1) Is a part developed in any given species in an extraordinary manner as compared with the development of the corresponding part in other allied species, more variable than parts which exhibit less specific peculiarity? (2) Which sex is the more variable? The species chosen is the moth *Thetus abboti*, in which the outer margins of the primaries are excessively irregular and extraordinarily long as compared with the other dimensions of the wings. Measurements were made, for a large number of specimens, of the length of the sinuous margin, the length and breadth of the wing, and the chord of the margin; and from these the author concludes that, in the moth in question, the most aberrant dimension of the fore wing is likewise the most variable, in accordance with Darwin's law. The females show, in general, a greater degree of variability than the males, but in the one markedly aberrant feature under discussion, their variability is less than that of the males. With reference to the first conclusion, the propriety may be questioned of instituting comparisons between the lengths of the jagged contour of the outer margin and the straight lines which determine the actual dimensions of the wings. Mr. Field might with advantage make observations on some other insect in which the length or breadth of the wing was the aberrant feature.

IN a long article (to be continued) contributed to the *Zoologist*, Mr. W. L. Distant reviews the facts and theories as to assimilative coloration, and propounds some new views. His remarks in the course of his paper "It seems possible that assimilative coloration may have been a first and very general consequent in animal development; that such a view is suggested by many facts; and that the subsequent protective resemblance acquired by numerous living creatures through the process of natural selection, when life had advanced to the competitive stage, is far too frequently used as an explanation for whole series of uniform phenomena in coloration, which have probably survived unaltered from remote antiquity, and which by their very essence were outside the law of natural selection, or unaltered survived as the 'fittest'."

THE *Biologisches Centralblatt* (No. 17) contains a paper by Hartvig Hutteldt-Kaas on the Plankton of the fresh-water lakes of Norway. The author follows the methods of Apstein, and finds that in general the Plankton is richer in shallow waters than in deep, except in regions where the rainfall is excessive, &c. where the lake is subject to sudden large additions to the volume of water. The seasonal variations in the quantity of Plankton in a number of lakes are exhibited graphically.

THE *National Geographic Magazine* for August contains a paper by Mr. W. J. McGee on Papaguera, the land of the Papago or Papaf Indians, an arid region lying beyond the Sierra Madre, partly in Mexico and partly in Arizona; and covering an area of about 50,000 square miles. The study of the natives presents some remarkable features, their whole existence may be said to be occupied with the search for water, and the tribe is distinguished by exceptional force and stability of character. More than three centuries of contact with white races has produced little or no effect upon them.

THE issue of the *Belgian Monteur International* of August 7 last is largely devoted to the new *Société Anonyme d'Etudes et d'Éditions Géographiques Elise Reclus*. The laws and constitution of the Society are printed in full, and there are special articles by M. Reclus and others. The new Society has for its object the furthering of geographical study and exploration in all directions, by means of co-operation with existing foreign institutions and with foreign branches of the Society itself; and special attention is to be given to the working up and publishing of geographical information relating to particular regions, in a form adapted for economic and commercial purposes.

THE number of the *Naturwissenschaftliche Wochenschrift* for September 11 contains an excellent popular account of the Adschidjarja, the gulf connected with the Caspian Sea by the narrow strait of Karabugas, and often known by the latter name. A current flows from the Caspian to the Adschidjarja, varying in speed at different seasons, but never changing its direction, and the waters of the gulf are intensely salt—28 per cent—compared with about 1·4 per cent. in the Caspian. Actual measurements made at different dates since its discovery in 1836 show that the Adschidjarja and the Karabugas are being rapidly filled up, and the fossil remains show that for a long period the waters of the former have been growing steadily saltier. The description of the chemical deposits, both organic and inorganic, is of extreme interest, the latter specially so in relation to the formation of oil bearing strata.

DR. H. CARRINGTON BOLTON has discovered in a cavern at Lake Minnewaska, New York, a grotto in which are reproduced on a small scale many of the beautiful phenomena seen at the celebrated Blue Grotto of the island of Capri. The lake is situated on the Shawangunk range of mountains at an elevation of about 1700 feet; it lies in a basin, excavated in glacial times, about half a mile long and less than a quarter in width, and of a depth reaching seventy feet. The rock on all

sides is a white quartzite, which rests upon shale, but no outcrop of the latter is visible at the lake. The water varies in colour from Nile green through turquoise blue and sky blue to deep indigo blue, and in all these shades exhibits the silvery appearance, when agitated, characteristic of the grotto at Capri. A body immersed in the water has a beautiful silvery sheen, similar to the reflection of moonlight. The water has these colours at all hours, but they are strongest when the sun is in the zenith, late in the afternoon the slanting rays of the sun enter the opening and light up the cavern, greatly diminishing the optical effects.

THE last two issues (vol. 1 Nos. 9 and 10) of the Records of the Botanical Survey of India comprise a contribution to the Botany of the Chitral Relief Expedition, 1895, by Mr. J. F. Duthie, and a Botanical Tour in Chamba and Kangra, by Mr. G. A. Gamble.

A VALUABLE list of the Freshwater Algae of Queensland is issued by the Department of Agriculture, Brisbane (*Botany Bulletin*, No. 15). The compiler, Mr. F. M. Bailey, has incorporated with his own observations those of the European algologists, Askenazy, Moebius, Nordstedt, Schmidt, and Borge, who have worked at the algology of Australia.

THE Geological Survey of Queensland (Department of Mines) has issued a list of Additions to the Fossil Flora of Queensland, compiled by Mr. John Shirley. The species described are mainly from the Ipswich formation, Trias-Jura system, and are mostly Gymnosperms and Pteridophyta, with a few Dicotyledones. The list is accompanied by twenty-five plates.

It is recorded in the *Queen Bulletin of Miscellaneous Information* (No. 140) that the Queen's Cottage Grounds (between 37 and 38 acres) have now been formally added to the precincts of the Royal Gardens, but that public access to them cannot be given until provision for their maintenance and supervision has been made in the estimates for the next financial year. It is intended to preserve the grounds as far as possible in their present condition.

THE numbers of the *Journal of Applied Microscopy* for June and July, published by the optical firm of Baush and Lomb, Rochester, New York, contain a number of very useful articles on microscopical technique, and on the structure of the microscope, as well as some which are more purely biological. The *Journal* should be in the hands of all microscopists.

THE *Biologisches Centralblatt* continues to publish useful epitomes of recent research in various branches of biological science. In the number for August 15 we find a paper, by Bernhard Jacobs, on the results of the newest researches on the locality and conditions of the formation of proteids in green plants, with a bibliography appended. The same number contains an article, by J. E. W. Hile, on the phylogeny and systematic position of the Pentapoda.

THE illustration of lectures and lessons by lantern slides is now so widely used, that attention may profitably be called to the supplementary list of slides just published by Messrs. Newton and Co. Among the lantern slides of interest to teachers of science, we notice in this list a set of 111 bacteriological slides, reproduced from original negatives by Dr. Satta; numerous recent astronomical photographs, including pictures of the Indian eclipse; views taken by Prof. Crookshank during the meeting of the British Association in Toronto last year; geological formations in the neighbourhood of Barmouth; and fifty-five pictures of English birds, photographed from the well-mounted specimens in the Natural History Museum. In addition to the titles of slides, the list contains descriptions of new lanterns and lantern accessories of service in science demonstrations.

THE additions to the Zoological Society's Gardens during the past week include a Chimpanzee (*Anthropopithecus troglodytes*, ♂) from West Africa, presented by Mr. Claude E. Bird, a Rhesus Monkey (*Macaca rhesus*, ♀) from India, presented by Mr. C. Ganz, a Brown Capuchin (*Cebus fatusellus*) from Guiana, presented by Miss May Hill, two White-throated Capuchins (*Cebus hypoleucus*) from South America, presented by Mrs. C. E. Cregan, three Black-eared Marmosets (*Leopoldina pinnulata*) from South-east Brazil, presented by Mrs. Dal Young; a Common Chameleon (*Chamaeleo vulgaris*) from North Africa, presented by Mr. W. E. Raynes-Cole; a Red-vented Bulbul (*Pycnonotus hamorrhous*) from India, deposited.

OUR ASTRONOMICAL COLUMN

ASTRONOMICAL OCCURRENCES IN OCTOBER —

- October 2 10h. 27m. to 11h. 35m. Occultation of 47 Arietis (mag. 5.9) by the moon
 4 Tempel's comet (1867 II.) due at perihelion
 5 9h. 46m. Minimum of Algol (β Persei)
 5 16h. 6m. to 17h. 27m. Occultation of 132 Tauri (mag. 5.1) by the moon
 7 Saturn Outer minor axis of the outer ring = 16" 09
 7 17h. 0m. Mars in conjunction with the moon (δ 1° 25' N)
 8 6h. 35m. Minimum of Algol (β Persei)
 13 11h. 0m. Jupiter in conjunction with the sun
 15 Venus Portion of illuminated disc = 0.521
 Diameter 34" 0
 15 Mars Portion of illuminated disc = 0.880
 Diameter 8" 0
 16 4h. 0m. Mercury 2' S of Jupiter
 18-20 Meteoric shower from Orion (radiant 91° + 15°)
 20 Perrine Chofardet's new comet due at perihelion
 22 3h. 44m. to 4h. 57m. Occultation of π Capricorni (mag. 5.2) by the moon
 22 5h. 5m. to 5h. 51m. Occultation of ρ Capricorni (mag. 5.6) by the moon
 23 5h. 13m. to 6h. 13m. Occultation of 18 Aquarii (mag. 5.4) by the moon
 24 Uranus 54' S. of β Scorpis
 27 5h. 0m. Venus at greatest brilliancy
 29 13h. 21m. to 14h. 10m. Occultation of μ Arietis (mag. 5.8) by the moon.

THE PLANET BETWEEN THE EARTH AND MARS.—Herr G. Witt, of the Urania Observatory, Berlin, is to be congratulated on the fortunate discovery he has made while searching photographically for minor planets. On August 14 last he found on the plate he had exposed, in addition to the trail of the minor planet he was hoping to catch, a second trail which indicated the presence of another of these small bodies moving round the sun with a more than usual velocity. Herr Witt was not content, however, to let the matter rest thus, so he undertook a series of eye observations and measurements which are necessary for the determination of the elements of the body in question. Herr Berberich undertook the task of investigating its motion from these observations, and the result, as far as is known, is surprisingly interesting. Instead of the object being a new or a previously observed member of that system of bodies which travels round the sun between Mars and Jupiter, it proves to be quite an exception, its orbit lying *within* that of Mars, in other words, it travels in a path which is nearer to the earth than that of Mars. It completes its revolution in a period of about 600 days; that is, roughly, 80 days less than Mars takes both the eccentricity and inclination of the orbit are considerable. This small body thus becomes our nearest neighbour after the moon, and, although small, will shine when closest to us as a star of the sixth magnitude. No doubt the discovery of this new planet will incite afresh observers of these small bodies, and who will say that this new object is the only member of its kind that performs its revolution round the sun in an orbit between the earth and Mars?

NO. 1509, VOL. 58]

PHOTOGRAPH OF THE CHROMOSPHERE.—In the *Astrophysical Journal* for August there is reproduced one of the photographs taken by Prof. Naegervald during the recent eclipse of the sun in January last. Prof. Naegervald, it will be remembered, was stationed at Jeur, and although his chief instrument (a six-inch Taylor Cooke triplet and two objective prisms of 45°) arrived from the makers as late as January 11, he was very fortunate in being able to adjust it as well as he did in the small amount of time he had at his disposal. The advantage of the prismatic camera over an ordinary slit spectroscope has during the late eclipse been abundantly proved, for one is easily able to differentiate at a glance between the spectra of the corona, the chromosphere and the prominences. There are, however, several points in photographs taken during an eclipse with such instruments which must be carefully considered, and which, when overlooked, are liable to lead to errors. An oversight of this kind occurs in the text describing the photograph referred to above. The writer states "Perhaps the most interesting feature of the photograph is the prominence shown in two lines between H and H_β, but invisible in H and K and the hydrogen lines."

A glance at the photograph tells us that the prominence is recorded in both the H and K light, but the peculiar position of the prominence in the spectrum is due to the fact that the two "lines" are the images of the upper portion of a prominence on the chromosphere obscured by the dark moon on the side opposite to that represented by the arcs. This same prominence is depicted on most of the negatives that were secured at Viznadrug, and is recorded not only in the H and K lines, but in the hydrogen and other lines.

OBSERVATIONS OF JUPITER DURING THE OPPOSITION 1898.—Sig. J. Comas Solá, observing at the Observatory of Calatá with an equatorial of 22 cm. aperture, made some very interesting observations of the surface markings on Jupiter during the period extending from January 18 to June 12 during the present year (*Astr. Nachr.*, 3519). The general aspect of the surface did not offer evidence of very great changes, but rather indicated that the planet was in a state of relative calm. More especially was this the case with the northern equatorial belt, which last year was very large, double and perhaps triple, but recently has been observed to be very simple, showing a uniform structure of a deep ruddy colour. The equatorial zone was found to be of an intense reddish yellow or yellowish orange colour, and was especially rich in details. In addition to the oblique grey markings usually seen, the whole zone appeared flaky, and when the definition was good this was found to be made up of large and small dark round spots. The south equatorial belt did not offer any new markings, but appeared in its normal condition. The red spot, according to Sig. Solá, was always very pale and grey, but in spite of its feebleness he could see the whole of its elliptic contour. The eastern portion always appeared darker than the rest, and sometimes a small dark spot could be seen in this position. From three transits of the eastern portion of this spot in April, May and June, the mean Jovian longitude was found to be 36° 5' for May 23. In the map showing the planisphere of this planet, which accompanies the article, the reader will gather a good general idea of the positions and shape of the markings which were seen by this observer.

PERIODICAL COMETS.—In the *Bulletin Astronomique* for September there is a most interesting article, by M. Schulhof, concerning periodic comets and the present state of theories connected with them. The article covers no less than forty-one pages of the *Bulletin*, so we cannot do more than give a very brief outline of its contents. M. Schulhof restricts his remarks simply to the movements of the comets and their accompanying perturbations, but does not touch on their chemical or physical characteristics. After a brief summary of the general ideas concerning the motions of each of these comets, and the part taken by the several investigators who have worked out the orbits, he draws attention to the great similarity between groups of comets, caused, as he mentions, by the presence of our planets exerting their influence as these bodies approach our system. The origin of comets and their relation to meteor swarms are further discussed, also the views of Schiaparelli, Faye, and Tisserand. In concluding, M. Schulhof makes mention of the difficulty connected with a complete reduction of the observations of a comet of short period, with which all computers are familiar, pointing out that the perturbatory actions of all the planets except Neptune have to be taken into account.

THE BRITISH ASSOCIATION.

SECTION H.

ANTHROPOLOGY.

OPENING ADDRESS BY E. W. BRABROOK, C.B., F.S.A.,
PRESIDENT OF THE SECTION.

I AM very sensible of the honour of presiding over this Section at a Bristol meeting. Bristol, from its association with the memory of J. C. Pritchard, may be regarded as the very birth place of British anthropology.

In submitting to this Section some observations on the past progress and the present position of the Anthropological Sciences, I use the plural term, which is generally adopted by our French colleagues, in order to remind you that Anthropology is in fact a group of sciences. There is what in France is called pure anthropology or anthropology proper, but which we prefer to call physical anthropology—the science of the physical characters of man, including anthropometry and craniology, and mainly based upon anatomy and physiology. There is comparative anthropology, which deals with the zoological position of mankind. There is prehistoric archaeology, which covers a wide range of inquiry into man's early works, and has to seek the aid of the geologist and the metallurgist. There is psychology, which comprehends the whole operations of his mental faculties. There is linguistics, which traces the history of human language. There is folk lore, which investigates man's traditions, customs, and beliefs. There are ethnography, which describes the races of mankind, and ethnology, which differentiates between them, both closely connected with geographical science. There is sociology, which applies the learning accumulated in all the other branches of anthropology to man's relation to his fellows, and requires the co-operation of the statistician and the economist. How can any single person master in its entirety a group of sciences which covers so wide a field, and requires in its students such various faculties and qualifications? Here, if anywhere, we must be content to divide our labours. The grandeur and comprehensiveness of the subject are among its attractions. The old saying, "I am a man, and therefore I think nothing human to be foreign to me," expresses the ground upon which the anthropological sciences claim from us a special attention.

I may illustrate what I have said as to the varied endowments of anthropologists by a reference to the names of four distinguished men who have occupied in previous years the place which it falls to my lot to fill to-day—most unworthily, as I cannot but acknowledge, when I think of their pre-eminence and qualifications. When the Association last met at Bristol, in 1875, Anthropology was not a Section, but only a Department, and it was presided over by Kollleston. There may be some here who recollect the address he then delivered, informed from beginning to end with that happy and playful wit which was characteristic of him; but all will know how great he was in anatomy, what a wide range of classical and other learning he possessed, and how he delighted to bring it to bear on every anthropological subject that was presented to his notice. In 1878 Huxley was the Chairman of this Department. It is only necessary to mention the name of that illustrious biologist to recall to your memory how much anthropology owes to him. Eight years before, he had been President of the Association itself, and seven years before that had published his "Evidence as to Man's Place in Nature." Brilliant as his successes were in other branches of scientific investigation, I cannot but think that anthropology was with him a favourite pursuit. His writings upon that subject possess a wonderful charm of style. In 1883 the Chairman was Pungelly, who for many years rendered service to anthropology by his exploration of Kent's Cavern and other caves, and who happily illustrated the close relation that exists between geology and anthropology. His biography, recently published, must have reminded many of us of the amiable qualities which adorned his character. Finally, in 1886, two years after anthropology had become a Section, its President was Sir George Campbell, a practical ethnologist, a traveller, an administrator, a legislator, a geographer, who passed through a long career of public life with honour and distinction. All my other predecessors are, I am glad to say, still living, and I make no mention of them. The few names I have cited—selected by the accidental circumstance that they are no longer with us—are sufficient to show what varied gifts and pursuits are combined in the study of anthropology.

There is another side to the question. Great as is the diversity of the anthropological sciences, their unity is still more remarkable. The student of man must study the whole man. No true knowledge of any human group, any more than of a human individual, is obtained by observation of physical characters alone. Modes of thought, language, arts and history must also be investigated. This simultaneous investigation involves in each case the same logical methods and processes. It will in general be attended with the same results. If it be true that the order of the Universe is expressed in continuity and not in cataclysm, we shall find the same slow but sure progress evident in each branch of the inquiry. We shall find that nothing is lost, that no race is absolutely destroyed, that everything that has been still exists in a modified form, and contributes some of its elements to that which is. We shall find that this, which no one doubts in regard to physical matters, is equally true of modes of thought. We may trace these to their germs in the small brain of the palæolithic flint-worker, or, if we care to do so, still farther back. This principle has, as I understand, been fully accepted in geology and biology, and throughout the domain of physical science—what should hinder its application to anthropology? It supplies a formula of universal validity, and cannot but add force and sublimity to our imagination of the wisdom of Great Nature. It is little more than has been expressed in the familiar words of Tennyson—

"Yet I doubt not thru the ages one increasing purpose turns,
And the thoughts of men are widen'd with the process of the suns,"

and supports his claim to be "the heir of all the ages, in the foremost files of time."

I propose, in briefly drawing your attention to some recent contributions to our knowledge, to use this as a convenient theory and as pointing out the directions in which further investigation may be rewarded by even fuller light.

Applying it, first of all, to the department of physical anthropology, we are called upon to consider the discovery by Dr. Dubois at Trinil in Java of the remains of an animal called by him *Pithecanthropus erectus*, and considered by some authorities to be one of the missing links in the chain of animal existence which terminates in man. In his presidential address to this Association last year, Sir John Evans said, "Even the *Pithecanthropus erectus* of Dr. Eugène Dubois from Java meets with some incredulous objectors from both the physiological and the geological sides. From the point of view of the latter the difficulty lies in determining the exact age of what are apparently alluvial beds in the bottom of a river valley." In regard to these objections, it should be remembered that though the skull and femur in question are the only remains resembling humanity discovered in the site, it yielded a vast number of fossil bones of other animals, and that any difficulty in settling the geological age must apply to the whole results of the exploration. The physiological difficulties arise in two points—do the skull and femur belong to the same individual? are they or either of them human, or simian, or intermediate? As to the first, it is true that the two bones were separated by a distance of about fifty feet, but as they were found precisely on the same level, accompanied by no other bones resembling human bones, but by a great number of animal remains, apparently deposited at the same moment, the theory that they belonged to different individuals would only add to the difficulty of the problem. With regard to the skull, a projection of its outline on a diagram comparing it with others of low type belonging to the stone age shows it to be essentially inferior to any of them. With regard to the thigh, you will recollect that at the Liverpool meeting of this Section Dr. Huxley displayed a remarkable collection of femora from the anatomical museum of Edinburgh University, exhibiting pathological and other conditions similar to those in the femur of Trinil. Though this evidence tends to show that the bone is human, it is not inconsistent with, but on the contrary goes to support, the conclusion that it belongs to an exceedingly low and ancient type of humanity. Whether, therefore, we call the remains *Pithecanthropus erectus* with their discoverers, or *Homo pithecanthropus* with Dr. Manouvrier, or *Homo Javaensis primitivus* with Dr. Houlié, we are in presence of a valuable document in the early evolution of mankind.

One element of special interest in this discovery is that it brings us nearer than we have ever been brought before to the time when man or his predecessor acquired the erect position. I believe that it is acknowledged by all that the femur belonged

to an individual who stood upright, and I presume that the capacity of the skull being greater than that of any known anthropoid is consistent with the same inference. The significance of that has been most clearly set forth by my predecessor, Dr. Munro, in his address to this Section at Nottingham in 1893. He showed that a direct consequence of the upright position was a complete division of labour as regards the functions of the limbs—the hands being reserved for manipulation and the feet for locomotion, that this necessitated great changes in the general structure of the body, including the pelvis and the spinal column; that the hand became the most complete and effective mechanical organ nature has produced, and that this perfect piece of mechanism, at the extremity of a freely moving arm, gives man a superiority in attack and defence over other animals. Further, he showed that, from the first moment that man recognised the advantage of using a club or a stone in attack or defence, the direct incentive to a higher brain development came into existence. The man who first used a spear tipped with a sharp flint became possessed of an irresistible power. In his expeditions for hunting, fishing, gathering fruit, &c., primitive man's acquaintance with the mechanical powers of nature would be gradually extended, and thus from this vantage point of the possession of a hand, language, thought, reasoning, abstract ideas would gradually be acquired, and the functions of the hand and the brain be developed in a corresponding manner. I do injustice to Dr. Munro's masterly argument by stating it thus crudely and briefly. It amounts to this—once the erect position is obtained, the actions of man being controlled by a progressive brain, everything follows in due course.

The next stage which we are yet able to mark with certainty as the palæolithic, but there must have been a great many intermediate stages. Before man began to make any implements at all, there must have been a stage of more or less length, during which he used any stick or stone that came to his hand without attempting to fashion the one or the other. Before he acquired the art of fashioning so elaborate an implement as the ordinary palæolithic axe or hammer, there must have been other stages in which he would have been content with such an improvement on the natural block of flint as a single fracture would produce, and would proceed to two or three, or more fractures by degrees. It must have been long before he could have acquired the eye for symmetry and the sense of design, of adaptation of means to ends, which are expressed in the fashioning of a complete palæolithic implement. It is probable that such rude implements as he would construct in this interval would be in general hardly distinguishable from flints naturally fractured. Hence the uncertainty that attaches to such discoveries of the kind as have hitherto been made public. Prof. McKenny Hughes, who speaks with very high authority, concludes a masterly paper in the *Archæological Journal* with the statement that he has "never yet seen any evidence which would justify the inference that any implements older than palæolithic have yet been found." The name "palæolith" which had been suggested for pre palæolithic implements seems to him unnecessary at present, as there is nothing to which it can be applied, and as it will be long before it can be asserted that we have discovered the very earliest traces of man, he thinks it will probably be long before the word is wanted. An elaborate work on the ruder forms of implement, just published by M. A. Thiéulien, of Paris, who has for many years been engaged in collecting these objects, adds materially to our knowledge of the subject.

Another line of argument bearing strongly in the same direction is afforded by the discovery in various places of works of art fabricated by early man. The statuettes from Brassempouy, the sculptures representing animals from the Bruniquel, the well-known figure of the mammoth engraved on a piece of ivory from Tucogot, and many other specimens of early art attest a faculty that it is not possible to associate with the dawn of human intelligence. M. Salomon Reinach tells an amusing story. A statuette in statuettes of a woman, resembling in some respects those of Brassempouy, was discovered in one of the caverns of Mentone, as far back as 1884, but when the discoverer showed it to a personage in the locality, that authority advised him not to let it be seen, lest it should take away from the belief in the antiquity of the caves, it being then thought too artistic to be consistent with early man. The finder acted on this advice, in ignorance of the real interest of the statuette, until April 1896, when he showed it to M. Reinach and M.

Villenois, who promptly interviewed the sage adviser in question, and obtained a confirmation of the statement. Some interesting additions to our gallery of prehistoric art have been recently made by M. Emile Rivière and M. Berthoumeyrou, at Cro-Magnon in the Dordogne. These are a drawing of a bison and another of a human female in profile, which M. Rivière has kindly allowed me to reproduce. Among the other objects found in the same place were some flint implements brought to a fine point, suitable for engraving on bone or horn.

The idea of making in any form a graphic representation of anything seen has never, so far as I know, occurred to any lower animal, and it could hardly have been among the first ideas formed in the gradually developing human brain. When that idea is found carried out with remarkable artistic skill, by means of implements well adapted for the purpose, we may surely assume that the result was not obtained till after a long interval of time, and was approached by gradual steps marked by progress in other faculties, as well as in the artistic faculty. It may be that some day all uncertainty on this head will be removed by decisive discoveries.

The interval between the Palæolithic and Neolithic periods rests in the like condition of incertitude. That by some means,

and somewhere on the face of the globe, the one period gradually passed into the other, we cannot but believe. That the transition between them may have involved innumerable degrees is also highly probable. Where and when, and how each step was taken we do not know at present, and possibly never shall know. The problem is not satisfactorily solved by the production of palæolithic implements resembling neolithic forms, or neolithic implements resembling palæolithic forms; inasmuch as between the one period and the other an interval of time involving geological and other changes has to be accounted for.

In this respect, also, our best authorities are the most cautious and conservative. In the excellent address which Prof. Boyd Dawkins delivered to the Royal Archaeological Institute at the Dorchester meeting last year, on the present phase of prehistoric archaeology, he contrasted the few primitive arts, such as sewing, and the manufacture of personal ornaments and rude implements of the chase, possessed by the palæolithic hunters—apart from their great proficiency in the delineation of animals—with the variety of arts, such as husbandry, gardening, spinning, weaving, carpentry, boat building, mining, and pottery making, possessed by the neolithic herdsmen, and held that between the

two there is a great gulf fixed. Somewhere that gulf must be bridged over. Prof. Boyd Dawkins says that the bridge is not to be found in the caverns of the South of France. It is difficult to meet his argument that the presence of grains of barley and stones of the cultivated plum at Mas d'Auzil are evidences of neolithic civilisation. His objections to other discoveries are not so strong as this, but are strong enough to make us pause. The tall, long-headed, people whose remains were found at Cro Magnon, he holds to be early neolithic and not palæolithic, to stand on the near side and not on the far side of the great gulf.

These considerations lend importance to the discoveries which have been laid before this Association at previous meetings by Mr. Seton-Kerr, and which have also been commented upon by Prof. Flinders Petrie and Sir John Evans. If we are compelled to admit a breach of continuity in Europe, is it in Africa that we shall find the missing links? That is another of the great problems yet unsolved. The evidence we want relates to events which took place at so great a distance of time that we may well wait patiently for it, assured that somewhere or other these missing links in the chain of continuity must have existed and probably are still to be found.

The next stage, which comprises the interval between the neolithic and the historic periods, was so ably dealt with by Mr. Arthur J. Evans in his address to this Section at the Liverpool meeting, that it does not call for any observations from me. Two Committees appointed by the Association in connection with this Section touch upon this interval—the Committee for investigating the lake dwellings at Glastonbury, and the Committee for co-operating with the explorers of Silchester in their well-conducted and fruitful investigation of the influence of Roman civilisation on a poor provincial population. I pass on to consider the very great progress that has been made of late years in some of the branches of anthropology other than physical and prehistoric, and especially in that of folk lore. I do this the more readily because I do not recollect that folk lore has ever before been prominently referred to in an address to this Section. It is beginning to assert itself here, and will in time acquire the conspicuous position to which it is becoming entitled, for the British Association is sensitive to every scientific movement, and responds readily to the demands of a novel investigation. Already, for three or four years, a day has been given at our meetings to folk lore papers, and at the Liverpool meeting an exceeding philosophic, and at the same time practical, paper was read by Mr. Gomme, and is printed in *extenso* in the *Proceedings* as an Appendix to the Report of the Ethnographic Survey Committee. The term "folk lore" itself is not without a certain charm. It is refreshing to find a science described by two English syllables instead of by some compound Greek word. The late Mr. W. J. Thoms had a happy inspiration when he invented the name. It is just twenty years since the Folk Lore Society was established under his direction. It has accumulated a vast amount of material, and published a considerable literature, it is now rightly passing from the stage of collection to that of systematisation, and the works of Mr. J. G. Frazer, Mr. E. Sidney Hartland, and others, are pointing the way towards researches of the most absorbing interest and the greatest practical importance.

A generalisation for which we are fast accumulating material in folk lore is that of the tendency of mankind to develop the like fancies and ideas at the like stage of intellectual infancy. This is akin to the generalisation that the stages of the life of an individual man present a marked analogy to the corresponding stages in the history of mankind at large; and to the generalisation that existing savage races present in their intellectual development a marked analogy to the condition of the earlier races of mankind. The fancies and ideas of the child resemble closely the fancies and ideas of the savage, and the fancies and ideas of primitive man.

An extensive study of children's games, which had been entered into and pursued by Mrs. Gomme, has been rewarded by the discovery of many facts bearing upon these views. A great number of these games consist of dramatic representations of marriage by capture and marriage by purchase—the idea of exogamy is distinctly embodied in them. You will see a body of children separate themselves into two hostile tribes, establish a boundary line between them, demand the one from the other a selected maiden, and then engage in conflict to determine whether the aggressors can carry her across the boundary or the defenders retain her within it.

There can be little doubt that these games go back to a high antiquity, and there is much probability that they are founded upon customs actually existing, or just passing away at the time they were first played. Games of this kind pass down with little change from age to age. Each successive generation of childhood is short—the child who this year is a novice in a game becomes next year a proficient, and the year after an expert, capable of teaching others, and proud of the ability to do so. Even the adult recollects the games of childhood and watches over the purity of the tradition. The child is ever a strong conservative.

Upon the same principle, next to children's games, children's stories claim our attention. Miss Ralston Cox has collected, abstracted, and tabulated not fewer than 345 variants of Cinderella, Catkin, and Cap o' Rushes. These come from all four quarters of the globe, and some of them are recorded as early as the middle of the sixteenth century. These elaborate stories are still being handed down from generation to generation of children, as they have been for countless generations in the past. Full of detail as they are, they may be reduced to a few primitive ideas. If we view them in their wealth of detail, we shall deem it impossible that they could have been disseminated over the world as they are otherwise than by actual contact of the several peoples with each other. If we view them in their simplicity of idea, we shall be more disposed to think that the mind of man naturally produces the same result in the like circumstances, and that it is not necessary to postulate any communication between the peoples to account for the identity. It does not surprise us that the same complicated physical operations should be performed by far distant peoples without any communication with each other, why should it be more surprising that mental operations, not nearly so complex, should be produced in the same order by different peoples without any such communication? Where communication is proved or probable, it may be accepted as a sufficient explanation, where it is not provable, there is no need that we should assume its existence.

The simple ideas which are traceable in so many places and so far back are largely in relation with that branch of mythology which personifies the operations of nature. Far be it from me to attempt to define the particular phases of it which is embodied in the figure of Cinderella as she sits among the ashes by the hearth, or to join in the chase after the solar myth in popular tradition. The form of legend which represents some of the forces of nature under the image of a real or fictitious hero capable of working wonders appears to be widely distributed. Of such, I take it, are the traditions relating to Glooscap, which the late Dr. S. T. Rand collected in the course of his forty years' labours as a missionary among the Micmac Indians of Nova Scotia, where, Mr. Webster says, Glooscap formerly resided. The Indians suppose that he is still in existence, although they do not know exactly where. He looked and lived like other men, ate, drank, smoked, slept and danced along with them, but never died, never was sick, never grew old. Cape Blomidon was his home, the Basin of Minas his beaver pond. He had everything on a large scale. At Cape Split he cut open the beaver dam, as the Indian name of the cape implies, and to this we owe it that ships can pass there. Spencer's Island was his kettie. His dogs, when he went away, were transformed into two rocks close by. When he returns he will restore them to life. He could do anything and everything. The elements were entirely under his control. You do not often meet with a mischievous exercise of his power. It is a curious part of the tradition, possibly a late addition to it, that it was the encroachments and treachery of the whites which drove him away.

The early inhabitants of the island of Tahiti appear to have had a whole pantheon of gods and heroes representing the various operations of nature. Even the Papuans have a legend in which the morning star is personified acting as a thief. But it is needless to multiply instances. Lord Bacon—who says "The earliest antiquity lies buried in silence and oblivion." This silence was succeeded by poetical fables, and these at length by the writings we now enjoy, so that the concealed and secret learning of the ancients seems separated from the history and knowledge of the following ages by a veil or partition wall of fables interposing between the things that are lost and those that remain"—has shown in his "Wisdom of the Ancients" that classical mythology was in truth a vast system of natural worship, and in so doing has done more than even he knew,

for he has affiliated it to those ideas which have been so commonly formed among rude and primitive peoples. It is true, he says, fables in general are composed of double matter, that may be drawn into great variety by a witty talent or an inventive genius, and be delivered of plausible meanings which they never contained. But the argument of most weight with him, he continues, "is that many of these fables by no means appear to have been invented by the persons who relate and divulge them, whether Homer, Hesiod, or others; but whoever attentively considers the thing, will find that these fables are delivered down and related by those writers, not as matters then first invented and presented, but as writings received and embraced in earlier ages. The relations drew from the common stock of ancient tradition, and varied but in point of embellishment, which is their own. This principally raises my esteem of these fables, which I receive, not as the product of the age, or invention of the poets, but as sacred relics, gentle whispers, and the breath of better times, that from the traditions of more ancient nations came, at length, into the flutes and trumpets of the Greeks."

Except that he supposes them to be a relic of better times, the poet's dream of a golden age no doubt still ringing in his ears, Bacon had, in this as in many other matters, a clear insight into the meaning of things.

Another idea that appears among very early and primitive peoples, and has had in all time a powerful influence on mankind, is that of a separable spirit. The aborigines of North-west Central Queensland, who have lately been studied to such excellent purpose by Dr. Walter Roth, the brother of a much-esteemed past officer of this Section, are in many respects low in the scale of humanity, yet they possess this idea. They believe that the ghost, or shade, or spirit of some one departed can so initiate an individual into the mysteries of the craft of doctor or medicine man as to enable him, by the use of a death-bone apparatus, to produce sickness and death in another. This apparatus is supposed to extract blood from the victim against whom it is pointed without actual contact, and to insert in him some foreign substance. They will not go alone to the grave of a relative for fear of seeing his ghost. It appears that they have the fancy that Europeans are ghosts. The Tasmanians also, as Mr. Ling Roth himself tells us, had the same fancy as to the Europeans, and believed that the dead could act upon the living. The *Pewee Indians*, we are assured by Mr. Grinnell, believe that the spirits of the dead live after their bodies are dust. They imagine that the little whirlwinds often seen in summer are ghosts. The Blackfeet think the shadow of a person is his soul, and that while the souls of the good are allowed to go to the sand hills, those of the bad remain as ghosts near the place where they died. The Shillooks of Central Africa are said to believe that the ghostly spectres of the dead are always invisibly present with the living, and accompany them wherever they go. The aborigines of Samoa believed in a land of ghosts, to which the spirits of the deceased were carried immediately after death. The religious system of the *Amazulu*, as described by Bishop Callaway, rests largely on the foundation of belief in the continued activity of the disembodied spirits of deceased ancestors.

Mr. Bryce, in his *Impressions of South Africa*, says that at *Lezumi*, in Mashonaland, are three huts, one of which is roofed, and is the grave of a famous chief, whose official name was *Makoni*. "On the grave there stands a large earthenware pot, which used to be regularly filled with native beer when, once a year, about the anniversary of his death, his sons and other descendants came to venerate and propitiate his ghost. Five years ago, when the white men came into the country, the ceremony was disused, and the poor ghost is now left without honour and nutriment. The pot is broken, and another pot, which stood in an adjoining hut, and was used by the worshippers, has disappeared. The place, however, retains its awesome character, and a native boy who was with us would not enter it. The sight brought vividly to mind the similar spirit worship which went on among the Romans, and which goes on to-day in China, but I could not ascertain for how many generations back an ancestral ghost receives these attentions—a point which has remained obscure in the case of Roman ghosts also."

The aborigines of New Britain are said to believe that the ghosts of their deceased ancestors exercise a paramount influence on human affairs, for good or for evil. They have the poetical idea that the stars are lamps held out by the ghosts to

light the path of those who are to follow in their footsteps. On the other hand, they think these ancestral ghosts are most malicious during full moon. Not to multiply instances, we may say with Mr. Stansland Wake, it is much to be doubted whether there is any race of uncivilised men who are not firm believers in the existence of spirits or ghosts. If this is so, and the idea of a separable spirit, capable of feeling and of action apart from the body, is found to be practically universal among mankind, and to have been excoverted by some of the least advanced among peoples, and if we observe how large a share this idea has in forming the dogmas of the most specialised religions of the present day, we shall not see anything inherently unreasonable in the generalisation that the group of theories and practices which constitute the great province of man's emotions and mental operations expressed in the term "religion" has passed through the same stages and produced itself in the same way from these early rude beginnings of the religious sentiment as every other mental exertion. We shall see in religion as real a part of man's organisation as any physical member or mental faculty. We shall have no reason to think that it is an exception to any general law of progress and of continuity which is found to prevail in any other part of man's nature.

The same inference may be drawn from many other considerations. Take, for instance, the belief in witchcraft, which is so characteristic of uncivilised man that it is hardly necessary to cite examples of it. The Rev. Mr. Collard, a distinguished missionary of the Evangelical Society of Paris, in a delightful record, which has just been published, of his twenty years' labours as a missionary pioneer among the Banyai and Barotzi of the Upper Zambesi, "on the threshold of Central Africa," says: "In the prison of the Barotzi, toiling at earthworks, is a woman—young, bright, and intelligent. She told me her story. A man of remarkably gentle character had married her. The king's sister, Katoka, having got rid of one of her husbands, cast her eyes on this man and took him. He had to forsake his young wife—quite an easy matter. Unfortunately, a little later on, a dead mouse was found in the princess's house. There was a great commotion, and the cry of witchcraft was raised. The bones did not fail to designate the young woman, and she was made a convict. A few years ago she would have been burnt alive. Ah, my friends, paganism is an odious and a cruel thing. Ah, Mr. Collard, it is many years ago that she would have been burnt alive or drowned in Christian England or Christian America? Surely the odiousness and the cruelty are not special to paganism any more than to Christianity. The one and the other are due to ignorance and superstition, and these are more hateful in a Matthew Hale or a Patrick Henry than in a Barotzi princess in the proportion that they ought to have been more enlightened and intelligent than she. It is only 122 years since John Wesley wrote: 'I cannot give up to all the Devils in Great Britain the existence of witchcraft,' and I believe that to this day the Order of Foresters is a recognised order in the Catholic Church."

The same line of argument—which, of course, I am only indicating here—might be pursued, I am persuaded, in numberless other directions. Mr. Fraser, in his work on the Golden Bough, has most learnedly applied it to a remarkable group of beliefs and observances. Mr. Hartland has followed up this research with a singularly luminous study of several other groups of ideas in the three volumes of his "Legend of Persius." More recently, Mr. Andrew Lang has sought to show that the idea of a Supreme Being occurs at an earlier stage in the development of savage thought than we had hitherto supposed. Striking as these various collations of facts and the conclusions drawn from them may appear, I am convinced there is much more for the folk-lore student in the same directions.

The principle that underlies it all seems to be this: man can destroy nothing, man can create nothing, man cannot of his own mere volition even permanently modify anything. A higher power restrains his operations, and often reverses his work. You think you have exterminated a race, you have put to the sword every male you can find, and you have starved and poisoned all the survivors of the community. In the meanwhile, their blood has been mingled with yours, and for generations to come your bones and those of your descendants will preserve a record of that lost race. You think you have exterminated a religion; you have burned to death all of its teachers you can find, and converted forcibly or by persuasion the rest of the community. But you cannot control men's thoughts, and the old beliefs and

habits will spring up again and again, and insensibly modify your own religion, pure as you may suppose it to be.

Huxley, in his address to the department of Anthropology twenty years ago, said, with the force and candour that were characteristic of him: "Anthropology has nothing to do with the truth or falsehood of religion—it holds itself absolutely and entirely aloof from such questions—but the natural history of religion, and the origin and the growth of the religious entertained by the different kinds of the human race, are within its proper and legitimate province." I do not presume to question that as an absolutely accurate definition of the position—it could not be otherwise; but if there be any here to whom what I have been suggesting is in any sense novel or startling, I should be glad to be allowed to say one word of reassurance to them. When my friend Mr. Clodd shocked some of the members of the Folk-lore Society by his frank statement of conclusions at which he had arrived, following the paths I have indicated, it was said we must fall back on the evidences of Christianity. What more cogent evidence of Christianity can you have than its existence? It stands to-day as the religion which, in most civilised countries, represents that which has been found by the operation of natural laws to be best suited for the present circumstances of mankind. You are a Christian because you cannot help it. Turn Mahometan to-morrow—will you stop the spread of Christianity? Your individual renunciation of Christianity will be but a ripple on a wave. Civilised mankind holds to Christianity, and cannot but do so till it can find something better. This, it seems to me, is a stronger evidence of Christianity than any of the loose jointed arguments I find in evidential literature.

Upon this thorny subject I will say no more. I would not have said so much, but that I wish to show that these considerations are not inconsistent with the respect I entertain, and desire now as always to express, for those feelings and sentiments which are esteemed to be precious by the great majority of mankind, which solace them under the adversities of life and nerve them for the approach of death, and which stimulate them to works of self-sacrifice and of charity that have conferred untold blessings on humanity. I reverence the divine Founder of Christianity all the more when I think of him as one who so well "knew what was in man" as to build upon ideas and yearnings that had grown in man's mind from the earliest infancy of the race.

To return. If continuity be the key that unlocks the receptacle where lie the secrets of man's history—physical, industrial, mental, and moral, if in each of these respects the like processes are going on—it follows, as I have already said, that the only satisfactory study of man is a study of the whole man. It is for this reason that I ask you to take especial interest in the proceedings of one of the Committees of this Section, which has adopted such a comprehensive study as the guiding principle of its work—I mean the Ethnographical Survey Committee. I have so often addressed this Section and the Conference of Corresponding Societies on the matter, since the Committee was first appointed at the Edinburgh meeting, on the suggestion of my friend Prof. Haddon, that I can hardly now refer to it without repeating what has been already said or forestalling what will be said when its report is presented to you, but its programme so fully realises that which has been in my mind in all that I have endeavoured to say that I must make one more effort to enlist your active interest in its work.

The scheme of the Committee includes the simultaneous recording in various districts of the physical characters, by measurement and by photography, the current traditions and beliefs, the peculiarities of dialect, the monuments and other remains of ancient culture, and the external history of the people. The places in the United Kingdom where this can be done with advantage are such only as have remained unaffected by the great movements of population that have occurred, especially of late years. It might have been thought that such places would be very few; but the preliminary inquiries of the Committee resulted in the formation of a list of between 300 and 400. So far, therefore, as the testimony of the very competent persons whose advice was sought by them is to be relied on, it is evident that there is ample scope for their work. At the same time, the process of migration from country to town is going on so rapidly, that every year diminishes the number of such places. One thinks with regret how much easier the work would have been one or two or three generations ago; but that consideration should only induce us to put it off no longer.

The work done by the lamented Dr. Walter Gregor for this Committee in Dumfriesshire and other parts of Scotland is an excellent type of the way in which such work should be done. His collections of physical measurements and of folk lore have been published in the fourth and fifth reports of the Committee. There can be no doubt that few men possess the faculty he had of drawing forth the confidence of the villagers and getting them to tell him their superstitions and their old customs. He succeeded in recording from their lips not fewer than 733 items of folk-lore. They not merely form exceedingly pleasant reading, such as is perhaps not often met with in a British Association report, but they also will be found to throw considerable light on the views which I have ventured to lay before you. It is much to be wished that others who have the like faculty, if even in a lesser degree, could be induced to take up similar work in other districts, now that Dr. Gregor has so well shown the way in which it ought to be done.

The work done by the Committee for the Ethnographical Survey of Canada; the completion of the Ethnographical Survey of the North western tribes which has been ably conducted for many years, and the progress made in the Ethnographical Survey of India will also be brought under your notice, the latter in a paper by Mr. Crooke, who has worked with Mr. Kistley upon it.

Another movement, which was originated by this Section at the Liverpool meeting, and was referred to in the report of the Council of the Association last year, has made some progress since that report was presented. Upon the recommendation of this Section, the General Committee passed the following resolution and referred it to the Council for consideration and action—

"That it is of urgent importance to press upon the Government the necessity of establishing a Bureau of Ethnology for Greater Britain, which, by collecting information with regard to the native races within and on the borders of the Empire, will prove of immense value to science and to the Government itself."

The Council appointed a Committee, consisting of the President and General Officers, with Sir John Evans, Sir John Lubbock, Prof. Tylor, and your esteemed Vice-President, Mr. Reid, the mover of the resolution. Their report is printed at length in last year's Report of Council, and shows clearly how useful and how easily practicable the establishment of such a Bureau would be. The Council resolved that the Trustees of the British Museum be requested to consider whether they could allow the proposed Bureau to be established in connection with the Museum. I understand that those Trustees have returned a favourable answer, and I cannot doubt that the joint representations which they and this Association will make to Her Majesty's Government will result in the adoption of a scheme calculated to realise all the advantages which we in this Section have so long looked for from it. The Secretary of State for the Colonies and the Chancellor of the Exchequer we have statesmen who cannot fail to appreciate the benefits the community must derive from acquiring accurate and scientific knowledge of the multifarious races which compose the Empire.

Those of us who visited the United States last year had the opportunity of observing the excellent work which is done by the Bureau of Ethnology at Washington, and those who stayed at home are probably familiar with the valuable publications of that department. An Act of Congress twenty years ago appropriated 40000 a year to the Smithsonian Institution for the continuance of researches in North American anthropology. The control of the Bureau was entrusted to the able hands of Major Powell, who gathered round him a band of skilled workers, many of whom had been previously engaged on ethnographic research under the direction of the Geographical and Geological Survey of the Rocky Mountain region. In field work and in office work, to use Major Powell's convenient distinction, ample return has ever since been rendered to the United States Government for the money thus appropriated, which has since been increased to 80000 a year. Our own Bureau of Ethnology would have a wider sphere of operations, and be concerned with a greater number of races. It would tend to remove from us the reproach that has in too many cases not been without foundation—that we have been content to govern races by the strong hand without caring to understand them, and have thus been the cause of injustice and oppression from ignorance rather than from malevolence. If that were only a record of the past, we might be content with mere unavailing regret; but the colonial

empire is still expanding, and we and our competitors in that field are still absorbing new districts—a practice which will probably continue as long as any spot of ground remains on the face of the globe occupied by an uncivilised race.

Would it not be worth while at this juncture to extend to the peoples of Africa, for instance, the principles and methods of the Ethnographic Survey—to study thoroughly all their physical characters, and at the same time to get an insight into the working of their minds, the sentiments and ideas that affect them most closely, their convictions of right and wrong, their systems of law, the traditions of the past that they cherish, and the rude accomplishments they possess? If for such a service investigators like Dr Roth, who began his researches in Queensland by so close a study of the languages and dialects of the people that he thoroughly won their confidence, could be found, the public would soon learn the practical value of anthropological research. If the considerations which I have endeavoured to urge upon you should lead not only the scientific student but the community at large to look upon that which is strange in the habits and ways of thinking of uncivilised peoples as representing with more or less accuracy a stage in that long continuity of mental progress without which civilised peoples would not be what and where they are, it could not but favourably affect the principles and practice of colonisation. *Tout comprendre c'est tout pardonner.* The more intimate our acquaintance with the races we have to deal with and to subjugate, the more we shall find what it means to stand with them on the same platform of common humanity. If the object of government be, as it ought to be, the good of the governed, it is for the governing race to fit itself for the task by laying to heart the lessons and adopting the processes of practical Anthropology.

PHYSICS AT THE BRITISH ASSOCIATION

THE reputation for industry which Section A has acquired in past years will not suffer in any way by the proceedings of the recent meeting in Bristol. In addition to the ordinary meetings of the Section, the International Magnetic Conference met on four days, and as all communications to the Section relating to terrestrial magnetism and atmospheric electricity were referred to the Conference, it may be said that the Section sat in duplicate for six days of meeting. On Saturday, when the Magnetic Conference did not meet, the two departments were devoted to mathematics and meteorology respectively, and on Wednesday the Section was not divided. On two occasions the Section was associated with others in joint discussions, namely with Section B, on the results of the recent solar eclipse expeditions, and with Section G, on the magnetic and electrolytic effects of electric railways. The members of the International Magnetic Conference also took part in the latter discussion. The papers read before the Section were representative of almost every branch of physics. In the following account they are grouped according to subject, and are not arranged in the order in which they were read.

Before the commencement of his address the President, Prof Ayrton, referred to the loss to science occasioned by the death of Dr John Hopkinson. The address, which was published in NATURE of September 8, suggests a new field for physical and chemical research, namely the investigation of the phenomena of smell. For the physicist the most striking experiments described are those which show the slowness of diffusion of odorous particles in still air, and the absorption of scents by glass, while the physiologist cannot fail to be interested in the superior sense of smell possessed by the female sex. In moving a vote of thanks to the President, Lord Kelvin referred to the identity of the senses of taste and smell, including both as the chemical sense, and hoped Prof Ayrton's address would lead to another bond of union between the chemist and the physicist. Prof Mascart seconded the vote, specially thanking the President for his welcome to the members of the International Magnetic Conference.

In the subject of heat Prof Rosa described the continuation of important work by himself and Prof Atwater, the object being to determine whether the law of conservation of energy holds good for the vital processes going on in the human body. For this purpose a space large enough for a man to live in was enclosed as a calorimeter, and surrounded by alternate jackets of flowing water and air, in such a manner that the heat evolved

from the "calorimeter" could be accurately measured. The details of construction of the apparatus were described at the Toronto meeting last year. During the past twelve months the authors have made experiments on men living in the calorimeter for periods varying from four to eight days, and doing different kinds of work. The heat-value of the food supplied and of the excreta were obtained by combustion, and the amount and composition of the gases entering and leaving the calorimeter were also determined. A full description of the work is to be published by the United States Government, under whose auspices the experiments have been carried out, it may, however, be stated that the law of conservation of energy is found to be true within the limits of experimental error. The ratio of the mechanical work done by a man to the total energy supplied to him, that is to say his efficiency as an engine, is usually about 7 per cent., and may be as high as 10 per cent. These figures are higher than the efficiency of a perfect heat engine working between the same limits of temperature, and lead us to the conclusion that the energy transformation in the human body is not effected solely by heat, but is most probably analogous to that in a circuit containing a battery and electromotor.

Another series of experiments to decide a question of theoretical interest was described in a paper by Dr A. Galt, on the heat of combination of metals in the formation of alloys. Lord Kelvin has shown how a lower limit to the size of atoms may be found by comparing the work done by the approach of the electrical charges on a thin film of zinc and a thin film of copper, their difference of potential being that due to contact, with the heat of combination of the films to form brass. On the other hand Prof Oliver Lodge has pointed out¹ that on the chemical theory of electromotive force of contact the heat of formation of an alloy should be much smaller than Lord Kelvin assumes it to be, and an exact determination of its value would form a crucial test between the rival contact and chemical theories. In Dr Galt's experiments a thin glass bulb with holes in its sides contains the alloy or the mixed metals, and is lowered into a calorimeter of glass containing nitric acid, as the acid passes through the holes the metal is dissolved, and the evolved gases do not escape. The rise of temperature of the acid is noted, and the heat of combination calculated. The results are so far preliminary, and the Association has made a grant for their continuation. Mr W N Shaw read a paper on Dalton's law, in which he called attention to Regnault's experiments on the pressure of mixtures of air and saturated ether vapour. These experiments show a discrepancy between the saturation pressure of ether in air and in a vacuum. The explanation afforded by Regnault is that errors are introduced owing to the condensation of vapour on the vertical walls of the barometer tube, but from experiments on mixtures of air and water vapour, Mr Shaw considers that a real departure from the law of Dalton is indicated. The subject is to be investigated in the Cavendish Laboratory. Dr C H Lees described experiments on the thermal conductivity of rocks at different pressures, according to which the conductivities of slates and granites are very slightly increased by increased pressure, while in the case of a rather soft sandstone the increase amounted to 3 per cent. under a pressure of about sixty atmospheres. Mr S R Milner and Prof Chattock read a paper on the thermal conductivity of water, which they find to be 0.0143 C.G.S. units at 20° C.

Among papers relating to light Mr J. W. Gifford read a communication on lenses, not of glass, in which he compared the transparency of calcite, quartz and fluor spar for extreme ultra violet rays, the last named being the most transparent. Lord Kelvin discussed the various theories of reflection and anomalous dispersion, and stated that none of the dynamical theories hitherto proposed is satisfactory or free from difficulties. Prof T. Preston described his experiments on radiation in a magnetic field. Zeeman found that when the spectrum of the sodium light emitted from a source in a magnetic field is viewed at right angles to the lines of force, the bright lines are tripled and the polarisation of the side lines is in a plane perpendicular to that of the central line. By using a very large grating and photographing the lines, Prof Preston finds that all bright lines in a spectrum are not treated alike; some are unchanged, some become doublets, triplets, quartets, or even sextets. He explained how absorption of the original radiation by vapour surrounding the source might account for the multiplication of lines, but he considers from the sharpness of definition of the lines that the effect is not due to absorption. Prof S. P.

¹ Philosophical Magazine, vol. xix, 1895.

Thompson described and exhibited an experiment by Right on the production of the Zeeman phenomenon by absorption. A beam of plane polarised white light is passed along the lines of force of a magnetic field, and received in an analyser adjusted to extinction with zero field, in the magnetic field is a sodium flame or a tube filled with nitric oxide. On setting up the field a brilliant yellow light is seen, which cannot be extinguished by rotating the analyser; spectroscopic examination shows it to consist of doubled sodium lines, the constituents of each doublet being slightly more and slightly less refrangible respectively than the original lines. In the case of nitric oxide the light seen is bluish green, being complementary to the colour of nitric oxide by transmission, and the spectrum consists of doublets. Profs. Lodge and Glazebrook thought that the phenomenon might be fully explained by supposing the magnetic field to alter the period of vibration of the ions so that they respond to waves of slightly higher or lower frequency than their natural one. Dr. C. E. Curry read a paper on the electromagnetic theory of reflexion on the surface of crystals.

A communication from Mr. J. Burke referred to the luminosity produced by striking sugar. The rim of a rapidly revolving disc of sugar is struck automatically by a hammer at the rate of about two blows per second, this causes an almost continuous luminosity extending from the hammer inwards and downwards. The spectrum of the light is confined to the more refrangible side of the F line, and the nature and appearance of the luminosity are unchanged by altering the medium surrounding the sugar. No satisfactory explanation of the phenomenon has yet been found.

The report of the Electrical Standards Committee is a record of progress made in the determination of the standard ampere. Profs. Ayrton and J. V. Jones have designed an ampere balance, for the construction of which a grant has been made by the Association. The details of the instrument were described to the Section. An appendix to the report contains an account of the determination of the temperature-coefficients of two coils used in the determination of the ohm by Profs. Ayrton and Jones, the measurements having been made by Mr. M. Solomon. The coils do not appear to have changed since 1896, but their resistances as measured in 1896 were slightly lower (0.006 to 0.007 per cent.) than the present values. The Electrolysis Committee has investigated the electrical conductivity and the freezing point of several dilute solutions of salts, which furnish some unexpected and, therefore, interesting results. The data are, however, not yet complete. The report was accompanied by a paper from Mr. Whetham on the measurement of the electric conductivity, and one from Mr. F. H. Griffiths on the freezing-point determinations. Mr. S. Skinner has investigated the carbon-consuming cell of Jacques, consisting of an iron crucible into which is put fused caustic soda with a carbon rod as electrode, the crucible forming the other electrode. In order to maintain the electromotive force of the cell, air is blown into the caustic soda. Mr. Skinner found that the arc acts by cleaning the surface of the iron crucible, and can be usefully replaced by adding sodium peroxide to the caustic soda. By measuring the current furnished by the cell, and the loss of weight of the carbon electrode per second, the author hopes to determine the electro-chemical equivalent of carbon. Messrs. Calvert and Donaldson communicated the results of some comparisons of the output and efficiency of a secondary cell (Tudor type) when charged at constant current and constant electromotive force respectively. By charging at constant potential the time of charging is reduced to less than half that required at constant current, the capacity is thirty per cent. greater, but the energy efficiency is ten per cent. less. Neither method of charging appears to damage the cell. Mrs. Ayrton read a paper on the drop of potential at the terminals of the electric arc, in which she described the exploration of potential distribution in the arc by means of a third electrode of carbon inserted laterally. If the arc be maintained at constant length the power expended at each carbon is a linear function of the current, and if the current be maintained constant the power expended at each carbon is a linear function of the arc-length. The experiments are subject to errors pointed out by Mrs. Ayrton in her paper: (1) the third carbon may not take up the potential of the point of the arc in which it is placed; (2) it alters the potential distribution and the length of the arc. The author proposes to repeat her experiments, using arc-insulating third carbon. Prof. Chattock described experiments to determine the velocity of

electricity in the electric wind. He finds that the electricity in the electric wind travels much more rapidly than the gaseous particles themselves, reaching in hydrogen a velocity of 900 cm. per second. Profs. Rosa and A. W. Smith have investigated the heating effect of alternating currents upon the dielectric of a condenser, measuring the net watts supplied to the condenser and the heat developed per second in the dielectric. Their results were communicated to the Section by Prof. Rosa. Mr. F. B. Fawcett described standard high resistances constructed by depositing cathode film on glass and heating them for a long time in a partial vacuum, this process renders them constant. Prof. Callendar exhibited a platinum voltmeter, in which the change of temperature of a platinum wire on passing a current through it is utilised to measure the current, and hence electromotive force, the instrument is made self-recording. Mr. E. H. Griffiths exhibited an apparatus for the measurement of resistance, by which the resistance of a coil can be measured to within one part in three millions. Prof. Lodge described a new magnifying telephone, for calling up the operator at the receiving end in systems of wireless telegraphy. The minute current set up in the receiving circuit passes through a small, light coil suspended in a strong magnetic field and rigidly attached to the disc of a microphone transmitter, the coil moves, and so sets the microphone disc in motion. A relay current in the microphone circuit is thus interrupted, and can be sent through the coil of a second similar apparatus. By using three or four magnifications a slight sound can be made to approximate in intensity to the human voice. Prof. Barrett, Messrs. W. Brown and R. A. Hadfield communicated the results of some determinations of the electrical conductivity and magnetic permeability of various nickel steels. Prof. S. Lemström and Dr. E. H. Cook read papers on the action of electricity on plants. Both agree that the growth of plants is accelerated by electrical discharges or currents. Dr. Cook, however, considers that the increased growth takes place only during germination of the seed and its growth underground, the mature plant being unaffected by electrical actions. In another paper Dr. Cook described experiments on the reflexion of the brush discharge.

The discussion on the magnetic and electrolytic action of electric railways was opened by Dr. S. Holt, who described the total destruction of two American magnetic observatories by the approach of electric street railways. Prof. Rüchler indicated disturbances of a magnetometer needle due to the South London Electric Railway felt as far away as 3½ miles, and referred to the complete destruction of the Greenwich vertical force and earth current records. He pointed out that the trouble could be remedied if electrical engineers would meet physicists in a friendly way, as they had done hitherto in this country. The principal disturbances arise from want of insulation of the return circuits of railway systems and the excessive distance between the outward and return circuits, the former gives rise to earth currents, and the latter to magnetic induction. Dr. Eschenhagen stated that in conjunction with Prof. von Bezold he had found a disturbance of magnetic instruments at a distance of 15 kilometres from electrical railways near Potsdam. Mr. W. H. Preece claimed protection for telegraphs and telephones as well as for magnetic observatories, the telephone, however, when provided with a complete twisted metallic circuit, is not capable of being disturbed, but earth currents due to leakage sensibly interfere with telegraphic work. Signor Palazzi described a method of damping the swings of a magnetometer needle so as to make it insensitive to small period oscillations. Prof. Fleming gave many instances of corrosion of gas and water pipes by electrolytic action, the pipes forming part of the earth return of a leaky circuit. Prof. S. P. Thompson suggested the use of alternating currents and no earth return, or of continuous currents with well insulated circuits and the return wire very close to the outward circuit. Prof. Ayrton pointed out that it was to the advantage of the electrical engineer himself to use a well insulated return circuit.

In the discussion on the results of the recent solar eclipse expeditions, Prof. Turner classified the work of solar eclipses as referring chiefly to the shape, movements, nature and brightness of the sun's surroundings. The success of Mrs. Maunder in photographing a long coronal streamer has led to a discussion on the efficacy of triple-coated plates and a small camera, such as she used. Again, evidence is very conflicting concerning the relations of coronal extensions and solar prominences, from their positions they appear to be connected, but spectroscopically there is no evidence of any such connection. Another

unsettled point is the question whether the corona takes part in the sun's rotation. Sir Norman Lockyer explained the connection between the spectra of stars and their temperature, and referred to the discovery that the spectrum of the sun's chromosphere is similar to that of the principal absorbing layer in γ Cygni, which he characterised as a Rosetta stone of solar and stellar spectroscopy. He showed how the spectra of the various layers of the chromosphere indicate a gradual increase of temperature from without inwards, and announced with reserve, that the Indian photographs suggested that the wave length of the chief coronal line required revision. Sir William Crookes suggested the appointment of a joint committee of chemists and physicists to examine quietly the question of solar spectra. Captain E. H. Hills exhibited his photographs of the spectrum of the inner corona. Captain Abney and Prof. Thorpe, who intended to take part in the discussion, were unable to be present at the meeting.

In meteorology, the Ben Nevis Committee sent a report of extended work, a station having been established at a point half-way up the mountain, and observations taken hourly during a portion of the year. The Committee on Meteorological Photography reported through Mr. Clayden that the work of simultaneously photographing clouds near the sun from two stations in an east and west line had been continued, the results showing that in hot, thundery weather the alto-cumulus and cirro-cumulus clouds attain great heights, sometimes reaching 90,000 feet. In order to make observations in the early morning and late afternoon a change of base line to a north and south direction is contemplated. The report of the Seismological Observations Committee deals with many phases of earthquake work, and in introducing it Prof. Milne emphasised the importance of securing better accommodation for seismological apparatus. He compared the seismological laboratories of Italy and Japan with the only one of this country, namely his own house at Shide, Isle of Wight. The Seismological Committee has taken steps towards securing the aid of the Government in providing suitable housing for seismological apparatus. The Montreal Meteorological Observatory reports having obtained successfully in McGill University Physical Laboratory records of the temperature on the top of Mount Royal, the installation of other apparatus recording at a distance is being proceeded with. Prof. Callendar described an application of his platinum thermometer as a sunshine recorder, by registering the temperature difference between a bright and a thickened thermometer. A. L. Roitch recorded an ascent of the Hargrave kite to a height of 11,440 feet at Blue Hill, Mass., U.S.A. Dr. van Ryckevorsel drew attention to a similarity, even in details, between the annual curves of temperature, air pressure, rainfall, magnetic declination, vertical and horizontal magnetic force. He considered this to be a proof of similarity of origin of magnetic and meteorological phenomena. Mr. Douglas Archibald indicated a classification of weather types in western Europe, lasting for several days, and thus permitting the possibility of extending the present daily forecast. Simultaneous telegraphic reports from a greater number of stations would be necessary. Mr. Hopkinson read a paper on the climate of south-western England.

Among papers on general physics, Mr. W. N. Shaw exhibited a pneumatic analogue of the potentiometer, in which air currents set up by gas jets at the lower ends of two tubes take the place of electric currents. The author pointed out its application to some problems of ventilation. Mr. A. W. Warrington described hydrometers of total immersion, which are hydrometers loaded with platinum weights and they are in the point of sinking; a slight rise of temperature of the liquid then causes them to do so.

For liquids, the method is accurate to one part in a million. For solids, a kind of Nicholson hydrometer without tray is used, and the temperature is determined at which the instrument has no weight in water (1) loaded with mercury alone, (2) loaded with the solid and mercury. The results are accurate to one part in 100,000. Mr. W. R. Barker described and exhibited some interesting old weights and measures of Bristol. In sound, if we except Lord Kelvin's communication on the continuity of undulatory theory for sound, elastic-solids and electric waves, the only paper presented was that of Dr. R. J. Lloyd on the articulation and acoustics of the spirate fricative consonants. In this paper the differences between the articulation and resonance of the consonants f , th , h , s , sh and ch are discussed, and the author points out that the first three differ in the length and width of the frictional passage of the throat producing them, whereas the last three require some kind of fore-cavity

which modifies and subdues the frictional noises. In the case of s and sh there is strong resonance from both the fore-cavity and the hinder cavity, the two sounds being differentiated by the second friction against the tips of the lower teeth in producing t . We shall take another occasion to refer to the proceedings of the Magnetic Conference.

During the meeting a collection of physical apparatus was exhibited in the physical laboratory of University College by Messrs. J. J. Griffin and Sons. It included an assay balance entirely free from steel, carrying 5 grammes and weighing to 0.00002 grammes, and a chemical balance weighing to 0.0001 grammes, both of which were provided with arrangements for weighing fractions of a gramme without opening the case. Holloway's crucible furnace, Davy's induction coil and X-ray bulbs, were also exhibited, as well as a simple form of apparatus for the measurement of expansion of solids, in which a rod fixed in a water bath between two glass rods is heated and displaces the glass rods, these pass through the sides of the water bath, and their displacement is measured directly by micrometer screws. The absence of optical devices for measurement increases greatly the simplicity of the instrument, which is said to yield fairly good results for lecture purposes.

MATHEMATICS AT THE BRITISH ASSOCIATION.

SATURDAY in the British Association week is a holiday for most of the Sections; the mathematicians and physicists, thus freed from competition, had for two audiences instead of one, and take papers on mathematics and meteorology in separate rooms. This year the mathematical session, over which Lord Kelvin presided, was very well attended.

The first paper, read by Colonel Allan Cunningham, was a report on the work of the Committee appointed some years ago, with Lord Kelvin as chairman, for calculating tables of certain mathematical functions. It was explained that a set of tables has been prepared, giving the residues of powers of 2 for all prime moduli less than 1000. The plan is much the same as that of Jacobi's Canon Arithmeticus; but Jacobi uses as base a primitive root of the prime number concerned, which is inconvenient in practical calculations. The tables are now complete in MS., and nothing remains but to print them. It is to be hoped that the Association will see its way to printing them separately in quarto, as their usefulness will be much diminished if they are printed on the smaller page of the Annual Report; but it seems likely that, partly for financial reasons, they will not be published at all for another year.

The next paper, "The mathematical representation of statistics," by Prof. Edgeworth, was read in abstract by one of the Secretaries, in the absence of the author, and the following one, "On the use of logarithmic co-ordinates," by Mr. J. H. Vincent, was taken as read, but is to be published in full in the Annual Report.

One seldom sees lantern illustrations to a paper read at the mathematical session. But the next two subjects on the list can be treated experimentally as well as mathematically. In the first, "A new method of describing cycloidal and other curves," Prof. Hele Shaw, of Liverpool, showed a new instrument for drawing the curves which can be got by rolling one circle on another. Perhaps its most striking feature is that the radii of the fixed and rolling circles may be as great as we please, their centres not being restricted, as in the ordinary instruments, to the limited range of a drawing board. Thus the radius of the fixed circle may be made infinite, when its circumference becomes a straight line, and the common cycloid is traced on the paper.

Another considerable advantage is, that the complete curve required can be drawn in many cases where the ordinary methods would only give a portion of it, or would only give the whole curve after several operations.

Since an ellipse of any eccentricity may be described by means of a point attached to a circle rolling within another of twice its diameter, it is clear that this instrument can be used for drawing ellipses. It differs from the lithograph of Messrs. Alexander and Thomson, which depends on the same property, in having two pairs of toothed wheels instead of one; this improvement gets rid of some of the defects of the older arrangement, with which ellipses can only be got under limited conditions.

The inventor expressed his opinion that mathematicians would

find this instrument a help in explaining to beginners the properties of roulette curves in general. While most teachers will probably reply that machines of this kind are more trouble than they are worth in teaching, no one will question their interest to the full-grown mathematicians themselves.

A second paper by the same author dealt with his experiments on the motion of a viscous fluid between two parallel plates. A remarkable theorem, due to Sir George Stokes, which was communicated together with the experimental paper, renders this work of great importance. In Prof. Hele-Shaw's arrangement, liquid is forced between close parallel plates, past an obstacle of any form; and the conditions chosen are such that, whether from closeness of the walls, or slowness of the motion, or high viscosity of the liquid, or from a combination of these circumstances, the flow is regular. This is best attained by using glycerine as the fluid; then by colouring the jets which enter between the plates at certain points, the lines of flow in the liquid are made visible, and can be thrown on a lantern screen or copied. Now Sir George Stokes's discovery is this, that the stream-lines thus experimentally obtained are the same as the stream-lines in the steady motion of a perfect (i.e. absolutely inviscid) liquid flowing past an infinitely thin long rod, a section of which is represented by the obstacle between the parallel walls which confine the viscous liquid. A complete graphical solution is thus experimentally obtained of a problem which, from its complexity, baffles the mathematician except in a few simple cases.

Owing to the similarity, so far as mathematics are concerned, between problems relating to the motion of a perfect fluid and the problems of electricity and magnetism this gives also a method of investigating electrical and magnetic problems, in which the effect of placing a body of any required form and resistance (ϵ with any value of μ) in a uniform field can be obtained.

The beauty of the experiments greatly interested the audience, many of whom were probably unable to follow easily Sir George Stokes's mathematics, it is to be hoped that some of the results will figure before long as diagrams in hydrodynamical text books.

Of the next paper, "Graphic representation of the two simplest cases of a single wave," by Lord Kelvin, an account will subsequently appear in these columns.

At meetings of the mathematical session in future years it is proposed to have a number of reviews of recent progress in various branches of pure mathematics, similar to those frequently prepared by German and American mathematicians. Several such reports are being arranged for next year, and this year a paper on "The recent history of the theory of the functions used in analysis" was given by Mr. E. T. Whittaker. The paper traced some of the more notable developments in the theories of special classes of functions, notably the automorphic functions and the functions of harmonic analysis. Then, speaking of the way in which most of the knowledge reviewed has been gained, "Isolated functions are invented, as Legendre's and Bessel's functions were invented, for the solution of physical problems. The work of the pure mathematician is to find the connection between them, to assign them places in an ordered series, and to develop their common theory. The arrangement once made, the gaps in the series are manifest. Every gap points to a function hitherto unknown, which is discovered and returned to the physicist, as the interest on his original deposit."

Two papers by Dr. Johnstone Stoney followed. The first, "The dynamical explanation of certain observed phenomena of meteor streams," attempts to account for the facts observed in meteoric showers on the earth, by considerations as to the streams of meteors which cause them. A shower may be very short, or it may last several days; its radiant—the point in the sky from which the stars appear to shoot—may remain fixed, or it may move; the disposition of the shower about its maximum may be symmetrical, or it may not; and in all these respects, the showers due to the same stream of meteors may behave differently in different years.

At each encounter of the meteors with the earth a number are caught and blaze themselves out in the atmosphere; a still larger number narrowly escape, and are deflected from their course by the earth's attraction. Dr. Stoney showed how the subsequent history of these "clino-meteors" will account for the facts noticed. This is especially interesting in view of our approaching encounter with the Leonid meteors.

In a second paper, "A survey of that part of the scale upon which nature works, about which man has some information," Dr. Stoney reviewed the range of our knowledge of magnitudes, and discussed what might be if the scale of our conceptions were of another order.

The last paper on the day's list was by Prof. G. J. Stokes, of Cork, on "The imaginary of logic." The search for a philosophical theory of $\sqrt{-1}$ has occupied men's minds ever since it was found that "impossible" quantities were useful. After classifying various views on the matter, the author said that the generally adopted position, that $\sqrt{-1}$ is uninterpretable in single or pure algebra, is paradoxical, for how can what is essentially meaningless possess an important meaning in its extraneous use? Then explaining the logical theory of the imaginary, he applied it to De Moivre's Theorem. The paper concluded with a comparison of the Calculus of Boole's Laws of Thought with that of Grassmann's Ausdehnungslehre, and some remarks on the relation of non commutative algebras to ordinary mathematics.

FORTHCOMING BOOKS OF SCIENCE.

IN the list of M. Félix Alcan (Paris) are to be found—*"Névroses et Idées Fixes,"* by Prof. Raymond and Prof. Pierre Janet, ii; *"Fragments de leçons cliniques sur les névroses, les maladies produites par les émotions, les idées, obsédées et leur traitement,"* *"L'Éducation de Sentiments,"* by P. F. Thomas, *"La Méthode dans la Psychologie des Sentiments,"* by Prof. F. Rauh, *"Opuscules de Taxinomie,"* by Durand de Gros, *"Chirurgie du péricarde et du cœur,"* by Prof. F. Ternier, *"L'audition et les organes,"* by le Dr. Uellé (Bibliothèque scientifique internationale), *"La céramique ancienne et moderne,"* by Guignot and Garnier (Bibliothèque scientifique internationale); *"La géologie expérimentale,"* by Prof. Stanislas Meunier.

The list of Messrs. Baillière, Tindall, and Cox includes—*"Aids to Psychological Medicine,"* by T. A. Beadle, *"Chronic Nasal Obstruction, and Deformities of the Upper Jaw, Teeth, and Palate,"* by Dr. M. P. Mayo Collier, *"Dictionary of Medical Terms,"* by H. de Méric, Part i, English French, Part ii, French-English, *"A Text book of Operative Veterinary Surgery,"* by Dr. George Fleming, Part ii, *"Cattle Tuberculosis, a Practical Guide to the Farmer, Butcher, Meat Inspector,"* by Dr. T. M. Legge, *"Aids to Materna Medicine,"* by Dr. W. Murrell, *"Essays for Students,"* by Stephen Paget, *"The Analysis of Food and Drugs,"* in five parts, by T. H. Pearson and C. G. Moor, Part ii, *"The Chemical and Biological Examination of Water,"* and new editions of *"Heart Disease, with Special Reference to Prognosis and Treatment,"* by Sir Wm. H. Broadbent, Bart., F.R.S., and Dr. J. F. H. Broadbent, *"The Throat and Nose and their Disease,"* by Lennox Browne, illustrated, *"Manual of Physiology, with Practical Exercises,"* by Prof. G. N. Stewart, illustrated, *"Handbook of Surgical Pathology,"* by Drs. W. J. Walsam and A. A. Canthack, *"Aids to the Diagnosis and Treatment of Diseases of Children (Medical),"* by Dr. J. McCaw, *"A Guide to the Examinations of the Conjoint Board in England, and for the Fellowship of the College of Surgeons, with Examination Papers,"* by F. J. Gant, *"Handbook for Attendants on the Insane, Prepared by Authority of the Medico-Psychological Association,"* *"Practical Guide to the Public Health Acts, and Correlated Acts for Officers of Health and Inspectors of Nuisances,"* by Dr. T. W. Hime.

Messrs. Blackie and Son, Ltd., promise—*"Recent Advances in Astronomy,"* by Dr. A. H. Fison; and *"The Science of Life,"* by J. Arthur Thomson.

Messrs. W. Blackwood and Sons give notice of—*"A Text-Book of Agricultural Zoology,"* by Fred W. Theobald, illustrated, *"Intermediate Text-Book of Geology,"* by Prof. Lapworth, F.R.S., founded on Dr. Pages' *"Introductory Text-Book of Geology,"* illustrated, and a new edition of *"Introductory Text-Book of Zoology,"* by Prof. Henry Alleyne Nicholson, F.R.S., and Alexander Brown, illustrated.

The list of the Cambridge University Press includes—*"Collected Mathematical Papers,"* by Prof. P. G. Tait; *"The Scientific Papers by John Couch Adams,"* vol. ii, edited by Prof. W. G. Adams and R. A. Sampson; *"A Treatise on Octonions,"* a development of Clifford's bi-quaternions, by Prof. Alexander McAlay, *"On the Kinetic Theory of Gases,"* by S. H. Burbury, F.R.S., *"A Treatise on Spherical*

Astronomy," by Prof. Sir Robert S. Ball, F.R.S., "A Treatise on Geometrical Optics," by R. A. Herman; "A Treatise on Dynamics of a Particle," by Dr. E. J. Routh, F.R.S.; "The Strength of Materials," by Prof. J. A. Ewing, F.R.S.; "Zoological Results based on material from New Britain, New Guinea, Loyalty Islands, and elsewhere, collected during the years 1895, 1896, and 1897," by Dr. Arthur Willey, the work will embody the zoological results of the expedition, and will, it is expected, be completed in five or six parts; it will be illustrated. "Fossil Plants," a manual for students of botany and geology, by A. C. Seward, F.R.S., in two vols., vol. II, "Vertebrate Paleontology," by A. S. Woodward; "The Soluble Ferments and Fermentation," by Prof. J. Reynolds Green, F.R.S. (Cambridge Natural Science Manuals, Biological Series) "Electricity and Magnetism," by R. T. Glazebrook, F.R.S. "Sound," by F. W. Capstick (Physical Series) "Crystallography," by Prof. W. J. Lewis; "The Principles of Stratigraphical Geology," by J. E. Marr (Geological Series) "Man, Past and Present," by A. H. Keane (Geographical Series) "An Introduction to Psychology," by G. F. Stout and John Adams; and "The Teacher's Manual of School Hygiene," by Dr. W. H. Hope and E. Brown.

In Messrs Cassell's list we find—"Wild Life at Home: how to Study and Photograph It," by R. Kearton, illustrated; and "Michael Faraday: his Life and Work," by Prof. Silvanus P. Thompson, F.R.S.

Messrs Chapman and Hall, Ltd., announce—"Wild Animals in Captivity," being anecdotes and reminiscences of the birds and beasts of the Zoological Gardens, with descriptions of their habits, food, management, &c., compiled from the notes and writings of A. D. Barette, and edited by his son, Edward Bartlett, illustrated. "Rambles in Lion Land," by Captain Francis B. Heaze, illustrated. "The Exploration of the Niger," a personal narrative of Lieut. Housie, commander of the 1895-96 expedition from Timbuktu to Bussa, translated by Mrs. Arthur Bell (N. D'Anvers), illustrated. "Medical Works of the Fourteenth Century," consisting of transcripts with notes, from four MS. volumes (contemporary with the works of Welfch and Chaucer), three being in the British Museum and one in the possession of Prof. Henslow, with an alphabetical list of upwards of 200 medical and other plants mentioned in the works of the fourteenth century, compiled and identified with their modern English and Latin equivalent names, by the Rev. Prof. George Henslow. "Measurement and Weighing," a first year's course in elementary practical physics, for organised science schools, by Edwin Fidler, and a new edition of "A Text Book of Mechanical Engineering," by Wilfrid J. Lineham.

Messrs J. and A. Churchill promise—"A Text Book of Materia Medica," by Prof. Henry C. Greenish, and new editions of Allen's "Commercial Organic Analysis," vols. I, II, III, Part I, Thresh's "Simple Method of Water Analysis," with a section added on "Sewage Effluents"; Morris's "Human Anatomy," Clouston's "Clinical Lectures on Mental Diseases," with nineteen plates, four of which are new, Taylor's "Manual of the Practice of Medicine," Hartridge's "Refraction of the Eye," and Goodhart's "Diseases of Children."

Among the books to be issued by the Clarendon Press may be mentioned a translation of Goebel's "Organographie der Pflanzen," by Prof. I. Bayley Balfour, F.R.S.

Messrs Duckworth and Co. promise—"Tom Tit Tot," an Essay on Savage Philosophy in Folk Tale, by Edward Clodd; "A Glossary of Botanic Terms," by B. Daydon Jackson; and "A Text Book of Agricultural Botany, Theoretical and Practical," by Prof. John Percival.

Messrs R. Friedlander and Sohn (Berlin) announce—"Icones Fungorum in Pannonia Observatorum," C. Chusius, Cum Commentariis mycologicis editis Prof. Gy. de Istváni, illustrated; "Das Tierreich," edited by the Deutschen Zoologischen Gesellschaft, General Editor, Franz Eilhard Schulze; Lieferung (5) Sporozoa, by Dr. A. Labbé; (6) Sarcopitidae et Demodicidae, by Prof. G. Canestrini and Prof. P. Kramer; (7) Pedipalpi et Scorpionidae, by Prof. R. Kraepelin; (8) Copepoda I., by Dr. W. Giesbrecht and Dr. O. Schmidt; (9) Trochilidae, by E. Hartert; (10) Hydrachnidia et Kinetidae, by R. Pierantoni and Dr. H. Lohmann; "Gerberti (Pape Sylvester II.) Opera Mathematica, primum collecta et edita N. M. Babnow," "Supplementum zum Zoologischen Adressbuch," edited by the Deutschen Zoologischen Gesellschaft; "Gesch-

ichte und Systematik der Indigo Synthese," Dr. A. Reimert; "Catalogus Mammalium tam viventium quam fossilium," Dr. E. L. Trouessart, v. Fasciculus, nova editio.

Messrs. Wells Gardner, Darton, and Co. promise—"Wonders of the Bird World," by Dr. R. Bowdler Sharpe.

The list of Messrs Gauthier Villars et Fils (Paris) contains—"Bibliographie générale de l'Astronomie," Houzeau et Lacoste, Tome in Observations, "Compositions d'Analyse, de Mécanique et d'Astronomie," Prof. E. Villet, III^e Partie; "Traité pratique de Radiographie et de Radioscopie," A. Londe; "Les Objectifs," P. Moessard; "Le développement de l'image latente, Théorie et pratique," A. Seyewitz; "Traité pratique de Photographie en relief et en creux," Léon Vidal; "La Photolithographie, la Photographie et leurs applications aux impressions monochromes et polychromes," Léon Vidal, and several volumes in the "Encyclopédie scientifique des Aide-Mémoire" Series.

The list of Messrs Gebirder Borntraeger (Berlin) includes—"Allgemeine Dermatologie oder Allgemeine Pathologie, Diagnose und Therapie der Hautkrankheiten," by Dr. Ernst Kromayer, and a new edition of "Flora des Nordostdeutschen Flachlandes (ausser Ostpreussen)," by Drs. P. Ascheron and P. Graebner.

The list of Messrs Ginn and Co. (Boston, Mass.) contains—"General Physics," by Prof. Charles S. Hastings and Frederick E. Beach, "Elementary Physical Geography," by Prof. William M. Davis, and a new edition of "Elements of the Differential and Integral Calculus," by Prof. James M. Taylor.

The list of Messrs. Charles Griffin and Co., Ltd., is as follows—"The Design and Construction of Locomotive Engines," with an historical introduction, by William Frank Pettigrew, with a Section on American and Continental Engines, by Albert F. Ravenshear, illustrated. "Esque-room Practice," by John G. Iversedge, illustrated; "Light Railways at Home and Abroad," by William Henry Cole, illustrated (Griffin's Engineering Series), "A Manual of Algebra," by Richard C. Buck; "A Text-book of Physics comprising Properties of Matter, Sound, Heat, Magnetism and Electricity, and Light," by Prof. J. H. Poynting, F.R.S., and Prof. J. L. Thomson, F.R.S., illustrated, (the volume on "Sound"), "The Metallurgy of Lead," by H. F. Collins, illustrated; "Dairy Chemistry for Dairy Managers, Chemists, and Analysts," by H. Droop Richmond (Griffin's Technological Manuals), "The Art of the Goldsmith and Jeweller," by Thos. B. Wigley, assisted by J. H. Stanbale, illustrated, "Atlas of Urinary Sediments with Special Reference to their Clinical Significance," by Dr. Hermann Kieder, translated by Dr. Frederick Craven Moore, edited and annotated by Prof. Delépine; "The Microbic Diseases of Animals," by Prof. Ed. Nocard and Prof. E. Leclanche, translated, with annotations and additions, by Prof. John Rose Bradford, F.R.S.; "The Diseases of Children," by Dr. George Elder and Dr. J. S. Fowler, illustrated, "Outlines of Bacteriology," by Dr. L. H. Thoinot and E. J. Massein, translated and adapted for English use, with additions, by Prof. Wm. St. Clair Symmers, illustrated, and new editions of—"The Chemistry of Gas Manufacture," by W. J. Atkinson Butterfield, illustrated, "Aids in Practical Geology," by Prof. Greenville Cole; "Januison's Elementary Manual of Steam and the Steam Engine," with many illustrations and examination questions; "Januison's Applied Mechanics (Introductory Manual), with numerous illustrations and examination questions; "Photography its History, Processes, Apparatus, and Materials," by A. Brothies, illustrated; "Mental Diseases with Special Reference to the Pathological Aspects of Insanity," by Dr. W. Bevan Lewis, illustrated.

Mr. Heinemann's list includes—"In the Forbidden Land," by Savage Landor, two vols., illustrated.

Messrs Hutchinson and Co. announce—"An Introduction to Stellar Astronomy," by W. H. S. Monck, "Drift from Longshore," by "A Son of the Marshes," "Fields, Factories and Workshops," by Prince Kropotkin; dealing with statistics, &c., on Agriculture, Manufactures and Trades "Disciples of Asculapius, Biographies of the Leaders of Medicine," by the late Sir W. Richardson, F.R.S.; "The Human Race," by Rev. H. N. Knollys, illustrated.

Messrs. F. King and Sons (Halifax) will issue to subscribers:—A new edition of "The Aborigines of Tasmania," by H. Ling Roth.

The Lippincott Company call attention to:—"A Laboratory Manual of Physics," by C. C. Balderston, illustrated; "Boilers

and Furnaces, considered in their Relations to Steam Engineering," by William M. Barr, illustrated; and a new edition of "A Text-book of Chemistry," by Dr. Samuel R. Sadtler and Henry Trimble, in two volumes, illustrated.

Messrs Crosby Lockwood and Son's announcements include — "Aerial or Wire Rope Tramways, their Construction and Management," by A. J. Wallis Taylor, illustrated; "The Marine Engineer's Guide to Board of Trade Examinations," by A. C. and E. W. I. Wannan, illustrated; "The Marine Engineer's Pocket Book," by A. C. Wannan; "Sewage its Treatment and Purification," by Dr. Sidney Barwise, illustrated; "Underground Steam Pumping Machinery," by Stephen Michell; and new editions of "Cyanide Process of Gold Extraction," by N. Eissler, "Baker's Land and Engineering Surveying," by F. E. Dixon.

Messrs. Longmans and Co. call attention to — "Psychology in the Schoolroom," by T. F. G. Dexter and A. H. Garlick; "A Treatise on Surgical Treatment," by Prof. W. Watson Cheyne, F.R.S., and Dr. F. F. Burghard, to be published in parts; "The Structure and Classification of Birds," by Frank E. Beddard, F.R.S., "An Epitome of Human Histology, for the Use of Students in connection with Lectures and Laboratory Work," by Dr. Arthur W. Weyse, "The Telephone. Outlines of the Development of Transmitters and Receivers," by Prof. William J. Hopkins, illustrated; "A Text-book of Theoretical Naval Architecture," by Edward Lewis Atwood; "My Inner Life, being a Chapter in Personal Evolution," by J. B. Crozier.

The announcements of Messrs Sampson Low and Co., Ltd., include, — "Burma," by Max and Bertha Ferraris, illustrated; "Portuguese Nyassaland, an Account of the Discovery, Native Population, Cultural and Mineral Resources, &c.," illustrated; "Photographic Optics," by R. S. Coles, with diagrams; "Manimalia of South Africa," by Dr. Selater; "Twentieth Century Practice," an international encyclopedia of modern medical science by leading authorities of Europe and America, edited by Dr. Thomas L. Stedman, vols. xv, xvi; "Child Culture in the Home," by Martha B. Moshier, and new editions of "Through the Yangtze Gorges Trade and Travel in Western China," by Archibald J. Little, illustrated; "How to Get Strong and How to Stay So," by W. Blaikie, illustrated.

The list of Messrs. Macmillan and Co., Ltd., includes — New volume of the Cambridge Natural History, vol. ix, "Birds," by A. H. Evans, illustrated; "A Manual of Zoology," by the late Prof. T. J. Parker, F.R.S., and Prof. W. A. Haswell, F.R.S.; "General Physiology, an Outline of the Science of Life," by Prof. Max Verworn, translated and edited by Dr. Frederic S. Lee, illustrated; "The Living Organism: an Introduction to the Problems of Biology," by Alfred Earl; "Elements of Palaeontology," by Prof. Karl A. von Zittel, translated and edited by Dr. Charles R. Eastman, this English edition is revised and enlarged by the author and editor in collaboration with numerous specialists; "Steam, Gas, and Oil Engines," by Prof. John Perry, F.R.S., illustrated; "A System of Medicine," by many writers, edited by Dr. Thomas Clifford Allbutt, F.R.S., vols. vi and vii; "Diseases of the Breast," by Dr. Maximo S. Sheld, "Vaccination with Special Reference to its Natural History and Pathology," Milroy lectures by Dr. S. Monckton Copeman; "The Witwatersrand Goldfields Basket and Mining Practice," by S. J. Truscott, with numerous plans and sections; "Australasian Goldfields," by R. Schmeisser, translated and edited by Prof. Henry Louis, illustrated; "A Text-Book of Metallurgy," by Carl Schnabel, translated and edited by Prof. Henry Louis, 2 vols., illustrated; "West African Studies," by Miss Mary Kingsley, illustrated; a translation of "In the Australian Bush and on the Coast of the Coral Sea, being the Experiences and Observations of a Naturalist in Australia, New Guinea, and the Moluccas," by Prof. Richard Semon, illustrated; "Observations of a Ranch-woman in New Mexico," by Mrs. Nicholl; the completion of "The History of Mankind," by Prof. Friedrich Ratzel, translated from the second German edition by A. J. Butler, 3 vols., illustrated; "The Valley of Light. Studies with Pen and Pencil in the Vaudois Valleys of Piedmont," by W. Basil Worsfold, illustrated; and new editions of "A History of Chemistry from the Earliest Times to the Present Day, being also an Introduction to the Study of the Science," by Prof. Ernest von Meyer, translated, with the author's sanction, by Dr. George McGowan; and "An Atlas of Practical Elementary Biology," by Prof. G. B. Hoves, F.R.S.

Messrs Methuen and Co.'s announcements include — "Through Asia," by Sven Hedin, 2 vols., illustrated; "The Highest Andes," by E. A. Fitzerald, illustrated; "Volumetric Analysis," by J. B. Russell; "Handbooks of Technology," "Carpentry and Joinery," by F. C. Webber, illustrated; and "Practical Mechanics," by Sidney H. Wells, illustrated; a new edition of "British Central Africa," by Sir H. H. Johnston, K.C.B., illustrated.

Mr. John Murray calls attention to — "Organic Evolution Cross examined, or, some Suggestions on the Great Secret of Biology," by the Duke of Argyll, K.G., F.R.S.; "The Tides and Kindred Phenomena in the Solar System," by Prof. George Howard Darwin, F.R.S., illustrated; "Early Chapters in Science," by Mrs. Audrey, illustrated; "Among the Celestials," abridged from "The Heart of a Continent," with additions, by Captain Francis Youngblood (illustrated); "Marine Boilers," a treatise on the construction and working of boilers of all classes, dealing more especially with recent developments of tubular boilers and the results obtained, based on the work of M. Bertin, translated and edited by Leslie S. Robertson, illustrated; "The Story of Marco Polo," for children and young people, edited by N. Brooks, illustrated; "The Five Windows of the Mind," by Edward Hamilton Aitken; "A History of Astronomy," by Arthur Berry (University Extension Manuals); "Colour in Nature," by Marion Newbould.

In Messrs T. Nelson and Sons' list we notice — "The White North, with Nordenskiöld, De Long, and Nansen," by M. Douglas.

Messrs. George Newnes, Ltd., announce — "Flashlights on Nature," by Grant Allen, illustrated; In the Library of Useful Stories — "The Story of the Cotton Plant, its Cultivation and the Manufacture of its Product," by F. Wilkinson, illustrated; "The Story of the Mind," by Prof. J. M. Baldwin, with diagrams; "The Story of the British Race," by John Munro, with maps; "The Story of Geographical Discovery. How the World became Known," by Joseph Jacobs, with maps, &c.; "The Story of the Metals," by H. C. Fyfe.

The announcements of Messrs C. Arthur Pearson, Ltd., include — "The Land of the Pygmies," by Captain Guy Barrows, illustrated; "Spinifex and Sand, a Narrative of five years' Pioneering and Exploration in Western Australia," by the Hon. David W. Carnegie, illustrated.

Mr. Young J. Pentland's announcements are — "Contributions to Clinical Medicine," by Dr. T. McCall Anderson; "Text-Book of Physiology," by British Physiologists, edited by Prof. E. A. Schafer, F.R.S., vol. ii; "Diseases of the Heart and Aorta," by Dr. G. A. Gibson; "The Principles of Treatment," by Dr. J. Mitchell Bruce; "Lectures on Giddiness and on Hysteria in the Male," by Sir Thomas Granger Stewart; "Text-Book of Medicine," by British teachers, edited by Dr. G. A. Gibson; "The Radical Cure of Hernia, Hydrocele, and Varicocele," by C. B. Lockwood; "Manual of Midwifery," by Dr. R. Milne Murray; "The Journal of Pathology and Bacteriology," edited by Dr. Sims Woodhead, vol. v, and a new edition of "The Principles and Practice of Medicine," designed for the use of practitioners and students of medicine, by Dr. William Osler, F.R.S.

Messrs G. P. Putnam's Sons announce — "Electricity in the Diagnosis and Treatment of Diseases of the Nose, Throat, and Ear," by Dr. W. Scheppegrell, illustrated; and a new edition of "Camping in the Canadian Rockies, an Account of Camp Life in the Wilder Parts of the Canadian Rocky Mountains, together with a description of the Region about Banff, Lake Louise, and Glacier, and a Sketch of the Early Explorations," by Walter D. Wilcox, illustrated.

The Reblman Publishing Company, Ltd., will issue — "Atlas of Legal Medicine," by Dr. E. R. von Hofmann, edited by Dr. Frederick Peterson; "Atlas of Laryngology," by Dr. L. Grünwald, edited by Dr. Charles P. Grayson; "Atlas of Operative Surgery," by Dr. O. Zuckerkandl, edited by Dr. J. Chalmers Da Costa.

Messrs. Lovell Reeve and Co., Ltd., announce — The fifth and the seventh volumes of the "Flora of Tropical Africa"; the seventh volume of the "Flora Capensis," the third volume of Mr. F. Moore's "Lepidoptera India"; the fifth volume of Mr. Barrett's "Lepidoptera of the British Islands"; and further instalments of Miss Bowdler Sharpe's "Teracoli" and Mr. Alfred Fryer's "Potamogeton".

Mr Grant Richards announces — "The Philosophy of Greece, considered in relation to the Character and History of the People," by Alfred W Benn.

Messrs. Routledge and Sons' list contains — New editions of Stonehenge, "The Horse," revised by Harold Leeney; and of "The Microscope" its History, Construction, and Application," by Dr. Jabez Hogg.

Messrs. Schleicher Frères (Paris) call attention to — "La Fatigue intellectuelle," by A. Binet and V. Henri, illustrated; "Contribution à l'étude de la Méthode dans les Sciences expérimentales," by Louis Favre; and "Traité complet des Variations du Système Musculaire de l'Homme et de leur signification au point de vue de l'Anthropologie Zoologique," by Prof. le Double.

Mr. Gustav Schmidt (Berlin) will issue — "Die Alpenpflanzen in der Gartenkultur der Tieflander," by Erich Wocke, illustrated.

The list of the Scientific Press, Ltd., is as follows — "An Atlas of Bacteriology," by Charles Slater and Edmund J. Spitta; "Hospital Expenditure the Commissariat," reprinted from the *Hospital*; "Some Medical Aspects of Education," by Dr. Percy G. Lewis; "The Burdett Series," — "The Rational Use of Antiseptics in Midwifery Practice," by Dr. James Morrison; "Nursing of Sick Children," by Dr. J. D. E. Mortimer; "Mental Nursing," by Dr. William Harding.

Messrs. Walter Scott, Ltd., promise — "The Natural History of Digestion," by Dr. A. Lockhart Gillespie, illustrated; "Degeneracy its Causes, Signs, and Results," by Prof. Eugene S. Tallot, illustrated (the Contemporary Science Series).

The S. P. C. K.'s list contains — "British Birds," by Dr. R. Bowdler Sharpe, illustrated in colours; "Matter, Ether, and Motion, the Factors and Relations of Physical Science," by Prof. A. E. Doolittle, with diagrams.

Messrs. Swan Sonnenschein and Co., Ltd., give notice of — "Aristotle's Psychology, including the *Parva Naturalia*," translated and edited, with Commentary and Introduction, by Prof. William A. Hammond; "Ethics," by Prof. W. Wundt, translated from the second German edition, vol. iii; "The Principles of Morality and the Sphere of their Validity," translated by Prof. E. B. Titchener; "Physiological Psychology," by Prof. W. Wundt, translated by Prof. E. B. Titchener, 2 vols. illustrated.

"History of Contemporary Philosophy," by Prof. Friedrich Ueberweg, edited by Prof. Max Heinke, translated by Prof. W. A. Hammond; "Text-Book of Paleontology for Zoological Students," by Theodore T. Groom, illustrated; "Text-Book of Embryology Invertebrates," by Prof. Konnecht and Heiler, vol. ii; "Crustacea and Arachnoids," translated by Matilda Bernard, and edited by Martin T. Woodward, illustrated.

"Elementary Text-Book of Botany," by Prof. Sydney H. Vines, illustrated; "Eclipses of the Moon from A.D. 300 to 1900," by Robert Sewell; "Common Salt, its Use and Necessity for the Maintenance of Health and the Prevention of Disease," by C. Godfrey Gumpel; "Fishes," by the Rev. J. A. Macpherson (Young Collector Series).

"Grasses, Handbook of," by W. Hutchinson, illustrated (Young Collector Series); "Mammalia," by the Rev. J. A. Macpherson (Young Collector Series); "Birds' Eggs and Nests," by W. C. J. Ruskin Butterfield (Young Collector Series); and new editions of "Text-Book of Embryology Man and Mammals," by Prof. Oscar Hertwig, translated by Prof. E. L. Mark, illustrated.

"Handbook of Practical Botany," for the Botanical Laboratory and Private Student," by Prof. E. Strasburger, edited by Prof. W. Hillhouse, illustrated; "Ants, Bees, Wasps, and Dragon flies," by W. H. Bath; and "Fungi, Lichens, &c.," by Peter Gray, in the Young Collector Series.

The list of Messrs. Thacker and Co. contains — "The Medical Monograph Series," edited by Dr. David Walsh. A new series of medical monographs, dealing with subjects of everyday practice, and embodying all recent scientific advances.

The announcements of the University Correspondence College Press include — "First Stage 'Physiology,'" "Botany," "Hygiene," "Inorganic Chemistry (Practical)," by Dr. F. Bedford; "Agriculture," "Advanced Magnetism and Electricity," by Dr. R. W. Stewart; "Advanced Inorganic Chemistry (Theoretical)," "Tutorial Algebra," Part II; "Advanced Course, Part I; "Elementary," by Wm. Briggs, and Prof. G. H. Bryan, F.R.S.; "Manual of Psychology," by G. F. Stout, vol. 1; "Text-Book of Botany," by J. M. Lawson, and "Introduction to Carbon Compounds," by Dr. F. Bedford.

In Mr. Fisher Unwin's list we find — "Through New Guinea

and the Cannibal Countries," by Captain H. Cayley-Webster; "The Psychology of Peoples," by G. Le Bon, translated by M. Dorech; and "Life of Man on the High Alps: Studies made on Monte Rosa," by Prof. A. Mosso, translated by Mr. and Mrs. Kiesow.

Messrs. Ward, Lock, and Co., Ltd., announce — "With Nansen in the North," by Lieut. Hjalmar Johansen, illustrated; and "Fishing and Fishers," by J. Paul Taylor.

Messrs. Whittaker and Co. will issue — "The Inspection of Railway Material," by G. R. Bodmer; "Electro Mechanical Science," adapted from the French of Henry de Graffigny by A. G. Elliot, vol. iii; "Electro-Chemistry," vol. iv; "Electric Distribution," "Central Station Electricity Supply," by Albert Gay and C. H. Yeaman; "Elementary Mathematics: Arithmetic, Geometry and Algebra," by J. L. S. Hutton and G. Bood; "Latent English and American," by J. Horner; "Electric Wiring, Fittings, Switches and Lamps," by W. Perren Maycock; "Outlines of Physical Chemistry," by Prof. A. Reychler, translated by Dr. J. McCrae; "Electric Traction," by J. H. Rider (Specialist's Series); "Horseless Road Locomotion" its History and Modern Development," by A. R. Bennett, 2 vols. illustrated.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE distribution of medals, prizes, &c. to students of the Royal College of Science, South Kensington, will take place on Thursday, October 6, at 2.30 p.m., in the Lecture Theatre of the Museum of Science and Art. Sir Norman Lockyer, K.C.B., F.R.S., will deliver an address upon this occasion.

DR. GEORGE KLEBS, professor of botany at Basle, has been called to Halle, and is succeeded at Basle by Dr. Wilhelm Schimper, assistant professor at Bonn.

DR. JAMES LYCHESTER, late chief lecturer on chemistry and metallurgy at the Merchant Venturers' Technical College, Bristol, has been appointed as head of the chemical department at the Municipal Technical College at Derby.

THE anniversary of the birth of Michael Faraday was commemorated on Thursday last at the "Michael Faraday" Board School, Waltham, by a gathering of the boys and girls of the upper standards in one of the large rooms to hear a commemorative address from Dr. Gladstone, F.R.S. A bust of Faraday which had been presented to the school by the Royal Institution was prettily decorated with plants brought by the children, and round the walls were cards giving some of the chief facts relating to Faraday's career. Every encouragement should be given to the adoption of such means as these for keeping in mind the work and high character of men like Faraday, and so inspiring a spirit of emulation.

THE following items from the *London Technical Education Gazette*, concerning the new session just commenced in the eleven polytechnics of London, are worthy of mention. — At Battersea Polytechnic special attention is being devoted to the organisation of preliminary courses in technical arithmetic, mensuration and elementary physics, chemistry and mechanics, adapted to the requirements of trade students. It is of great importance that young students before commencing the regular technical and trade classes should be provided with a sound elementary training in the above subjects. The syllabus recently issued by the Technical Education Board has called attention to the need for such instruction, and at many of the polytechnics and technical institutes students can now find opportunities for acquiring it. — Among the principal developments at the Borough Polytechnic is a new bakery, which has been built and equipped in the most complete manner, and provides exceptional accommodation and facilities for the teaching of baking. A new physical laboratory has also been erected. — At the Woolwich Polytechnic great additions have also been made last season by the erection of a new wing containing chemical and physical laboratories and increased accommodation for art teaching. A special laboratory has also been erected for the teaching of mechanical engineering, a subject which is naturally much in demand among the employees of the Arsenal. — In the day engineering department at the South-Western Polytechnic a civil engineering section has been added to the sections for mechanical and electrical engineering. — At the Regent Street Polytechnic a

new departure has been made by the establishment of a school for carriage builders.—The opening of the new session at the Northampton Institute is marked by several important developments. Rooms have been specially fitted up for the teaching of electro-chemistry in special relation to the trades of the district, and valuable courses in electrolysis, electro-plating and electro-typing have been arranged. A metallurgical department has also been established, and a special laboratory has been fitted up in connection with it. Special classes for opticians have been arranged in conjunction with the Speetalemakers' Company, a laboratory has been equipped for the practical teaching of optics, and a graded series of examinations has been drawn up.

THE work of the two London polytechnics which are independent of the Board's Technical Education aid, the East London Technical College and the Goldsmiths' Institute, continues to show increased activity. In the chemical department at the Goldsmiths' Institute a special course has been organised for brewers and sugar refiners, while the art department continues to take a leading position among the art schools of the country. At the East London Technical College (People's Palace) last year's work has been marked by conspicuous success, the college having secured an open science scholarship at Merton College, Oxford, two Whitworth exhibitions of 50*l.*, and two National scholarships, besides numerous other distinctions.

A SERIES of articles upon Dr John Radcliffe, the generous benefactor of Oxford University, has recently appeared in the *Pharmaceutical Journal*. Radcliffe was born in 1650, the year after the execution of Charles I. He went to London in 1684, and rapidly became a most successful, though eccentric, physician. He died in the year 1714, leaving the great bulk of his large fortune, consisting of money and of lands and houses in Yorkshire, Northamptonshire, Bucks, and Surrey to Oxford University. He bequeathed 40,000*l.* to build a library in Oxford, with 150*l.* a year for the salary of the librarian, and another yearly 100*l.* for the purchase of books. The Radcliffe Library, one of the finest buildings in Oxford, was opened in 1749, and furnished mainly with medical and scientific books. The building has since been annexed to the Bodleian as a reading room, when the contents of the library, greatly increased in the course of years, were transferred to a building specially affected to them in the new University Museum. It is now a magnificent collection of books on medical, physical, natural, biological and general science, kept up to date, easily accessible, and has given a considerable impulse to scientific study at Oxford. In order to make provision for select Oxford alumni studying medicine, to learn what was doing in medical science abroad, Radcliffe made over for ever to his own first and favourite Oxford College—University—his Yorkshire estates, for the foundation of two travelling fellowships of 300*l.* a year each and tenable for ten years, to be given to carefully selected alumni studying medicine at Oxford. At present there are three such Radcliffe travelling fellowships, with an annual income of 200*l.* each and tenable for only three years instead of the original ten. Besides this he left 5000*l.* to enlarge the buildings of University College. Any surplus accruing from the Yorkshire estates after the foregoing objects were effected was to be applied to the purchase of advowsons to be given to members of University College. Finally, mention of minor benefactions to Oxford and to individuals being omitted, he left, after payment of his specified bequests, all his estates in the various counties already enumerated to trustees to be applied to such useful purposes as they in their discretion should think best. And well have the Radcliffe trustees fulfilled their duty, remembering the claims both of philanthropy and science. With the funds at their disposal was built the Oxford Public Infirmary, opened for the reception of patients in 1770, and the Radcliffe Observatory at Oxford, supplied with all the instruments and appliances of modern astronomy, and a dwelling house for the Observer.

SCIENTIFIC SERIALS.

American Journal of Science, September.—Transition temperature of sodic sulphate, a new fixed point in thermometry, by T. W. Richards. Sodium sulphate, $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$, "melts" at almost exactly 32.48° according to the mean mercury thermometer, and this temperature is so easily obtained by means of that salt and so constant as to be of great use

in the future for thermometric and thermostatic purposes.—Distribution and quantitative occurrence of vanadium and molybdenum in rocks of the United States, by W. F. Hillebrand. Vanadium occurs in quite appreciable amounts in the more basic, igneous and metamorphic rocks, up to 0.08 per cent or more of V_2O_5 , but seems to be absent or nearly so, from the highly siliceous ones. The heavy ferric aluminous silicates like biotite and amphibole are indicated as sources. Molybdenum is probably confined to the more siliceous rocks, where it occurs in very minute quantities.—Electrosynthesis, by W. G. Mixer (second paper). Gaseous mixtures are subjected to a glow discharge in a eudiometer. Concentration of the discharge does not affect the total amount of compound formed. Thus, a mixture of hydrogen and oxygen will give the same amount of water vapour whatever the form of the glow discharge. The combination increases with the pressure, but not in proportion to it. A mixture of oxygen and ammonia forms ammonium nitrate, which is deposited as a white coating.

—Notes on species of *Ichthyodactylus*, including the new species *I. cruentatus*, and on the related and herein established genus *Gillicus*, by O. P. Hay. The supposed new species is primarily founded on a somewhat imperfect left maxilla from Butte Creek Canyon in Western Kansas. It differs from *Gillicus* *I. anadensis* in having larger teeth. For Cope's *I. aratus* and Crook's *I. polymorphus* the author proposes the new generic name *Gillicus*, being a saurocephalid with maxilla falciform, relatively short (gap of mouth smaller than in *Ichthyodactylus*).—Origin and significance of spines, by C. E. Beecher (continued). Natural selection could not originate a spine, but after a spine had appeared this agency would tend to preserve and allow the spine to develop along certain lines. The simple antlers of the Tertiary deer may have reached the highest degree of efficiency as weapons by ordinary natural selection. The subsequent increasing complexity of the antlers cannot have improved their usefulness, and probably arose according to the law of multiplication of effects, aided by a process of sexual selection.

Symons's Monthly Meteorological Magazine, September.—British local meteorological publications. Some important additions have been made to the list given in the last number of this journal, among which we may mention (1) an annual report of about thirty pages, by M. Chanut, Baron of France,ologist of Torquay, and a separate report on the climate of Devon, (2) a valuable summary of all Mann meteorological observations, by Mr. A. W. Moore, and (3) some remarks on the climate of Oban, with averages for the ten years 1887-96, by the Medical Officer of Health.—Evaporation and temperature, by Prof. Carpenter. This is an abridgment of a paper in the *U.S. Monthly Weather Review* of May 1898, showing the difficulty of determining from ordinary observations of the vaporimeter the quantity of water added to the atmosphere daily by evaporation from the oceans, lakes and continents. The principal elements of uncertainty in determining the quantity of evaporation from a surface of water are the temperature of the water and the velocity of the wind at the surface.—Rockall. The August number of the *Scottish Geographical Magazine* contains an excellent account of this rocky islet, by Mr. M. Christy. The possibility of building a lighthouse and observatory, and connection by a telegraphic cable, is discussed. The value of the latter would be very great for the purpose of weather telegraphy, but at present the difficulty of expense is insurmountable.—Results of meteorological observations at Camden Square, London, in August, for forty years, 1858-97. The mean of all the highest maxima was 84.0° , and the mean rainfall was 39 inches, in this year the maximum temperature reading was 87.9° , and the rainfall 1.18 inches.

THE nineteenth volume of the *Memoirs of the Caucasian branch of the Russian Geographical Society* is perhaps even better than its remarkably good predecessor. Its chief feature is a map, on the scale of 10 miles to an inch, of Transcaucasia, upon which all the divisions into provinces, districts, cantons and villages are given, and the religions of the inhabitants of each village are shown in different colours. The map is accompanied by full ethnographical-statistical lists of the whole population. The next map of great interest is one of Kurdistan, upon which the distribution of the Kurd population (the Sunnites, the Kizilbashs, and the Yezidi separately) is shown, together with the Armenians and Nestorian population and the percentage of Christians in each separate district. This map accompanies a paper, by Colonel Kartseff, on the Kurds,

in which their geographical distribution, their division into stems, their history, and their present institutions and general conditions are discussed. In the same volume we find a most valuable list of 597 trigonometrically-determined spots in Transcaucasia and the Terek province, with their latitudes, longitudes and altitudes, indexed according to latitudes and alphabetically, four very good geographical, economical and statistical descriptions of the provinces of Stavropol, Terek and Zakatlay, with a map of the province of Stavropol giving the distribution of landed property, an interesting paper on the forests, the forestry, and the inhabitants of the woodlands of Ichkeria, in Daghestan, and a list of the Alpine plants (270 species) of Central Caucas, by Prof. Alkneff—the result of seven years' work. In an appendix we find two long papers, one, by N. Dinuk, containing a graphic account of his Caucasian journey—this time to the head waters of the Urushten and Byelaya rivers (with a large scale map, 3½ miles to the inch), and another, on the common law of the Swanes, their habits and customs, written by such an excellent authority on this subject as Prince Raphael Brissot.—The twentieth volume of the same periodical, just received, contains an admirable map of all Caucasus and Transcaucasia, with very carefully drawn mountains, on the scale of 27 miles to the inch. It accompanies the first instalment of a work, "Transcaucasia," in which Colonel Litsvsky gives a general physical geographical description of Transcaucasia—its physical features, its geology, its vegetation, and its animal world.

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, September 19.—M. Wolf in the chair.—On the clinical value of the agglutination of Koch's bacillus by human blood serum, by MM. S. Arlong and Paul Courmont. The results of over one hundred cases show that the aggregation of the tubercle bacilli when the blood serum is introduced into a culture may furnish, very rapidly, an important element of information in the early diagnosis of true tuberculosis. There were, however, two remarkable cases where the test failed, though tuberculosis was undoubted and in an advanced stage. The fact that positive results were almost always obtained when the tuberculous lesions were in an early stage renders the serum reaction the more valuable. Feeble aggregation was induced in some cases where tuberculosis was not found by the ordinary clinical methods, and the inference is drawn that latent tuberculosis may be consistent with the appearance of perfect health. One of the latter cases afterwards developed into tubercular laryngitis.—Observations and elements of the Perrine-Chofardet comet by M. G. Fayet.—Observations on the Perrine Chofardet comet, made with the large equatorial at the Observatory of Bordeaux, by MM. L. Picart and Courty.—Synopsis of the solar observations made at the Royal Observatory of the Roman College during the first quarter of 1898, by M. P. Tacchini.—On the colorations of the less fusible porcelain enamels, by MM. A. Le Charpentier and P. Charpy. A list of the colours obtainable from various metals, all of which have been tested upon the manufacturing scale. The compositions are given of erbium and neodymium blue, erbium and neodymium greens, neodymium violet and erbium red.—Influence of gravity and light upon the down-central organisation of the branches in infereferences, by M. H. Ricome.—On the balloon ascents of June 8, 1898, on the occasion of the fourth international experiment, by MM. Hermite and Besançon.

GOTTINGEN

Royal Society of Sciences.—The *Nachrichten* (Mathematico-physical Section), part 2 for 1898, contains the following memoirs communicated to the Society:—

April 30.—W. Voigt. Thermo dynamical contributions on the interrelations of galvanism and heat.
May 14.—E. Riecke. Second memoir on the theory of galvanism and heat. W. Voigt. On the magnitude of the stresses and strains involved in the production of shearing in Iceland spar. E. Marx. The dispersion of the electrical spectrum of water. P. Stachel. On transformations of motions.
June 21.—W. Voigt. Is the pyroelectricity of crystals entirely referable to piezoelectric action?

June 25.—E. Riecke. The reactive pressure of kathode rays. J. Orth. Fifth report on the work of the Göttingen Pathological Institute.

NORTH AMERICAN BIRDS

Bird Studies, an Account of the Land Birds of Eastern North America By W. E. D. Scott 4to, pp. xii + 363 (New York and London G. P. Putnam's Sons, 1898)

IF it be permissible to judge from the books with which they are respectively supplied, there must be an inherent constitutional difference between the English and the American reader of popular bird-lore. In almost all the numerous works written for the benefit of the former there is a more or less rigid adherence to a systematic arrangement of some kind or other. As we have had previous occasion to remark, American books, on the other hand, are characterised by their partiality for methods of arrangement other than systematic. Personally we confess to a deep-rooted prejudice in favour of the English plan; but if American readers find this too cut and dried for them, and prefer some less inelastic classification, little fault can be found with the writers who endeavour to gratify their taste.

In his preface the author tells us that the present volume is an invitation to a more intimate acquaintance with the land birds of Eastern North America. And since under that somewhat vague geographical expression he includes not only the portion of the continent lying east of the Mississippi together with Lake Winnipeg and the western border of Hudson Bay, but also the whole of Greenland and the islands which naturally group themselves with the mainland of the region, it is obvious that the fauna to be dealt with is a very extensive one.

In place of a systematic classification, the birds, which range from the ordinary song-birds to the quails, have been made to group themselves around a series of familiar stations. We have, in the first place, the birds frequenting the house and homestead, followed by those to be met with along the highways and lanes, and these again succeeded by the denizens of the woods and the inhabitants of fields and meadows. Finally, we have the marsh and swamp birds, together with those to be found along the margins of streams and ponds. Not that the true water-birds are included, since of these the author proposes to make a companion volume, should his present effort meet with a satisfactory reception on the part of the public. At the end of the volume is given a systematic table of all the species treated.

If a miscellaneous arrangement of some kind or another be inevitable, the one selected is, perhaps, among the least open to criticism. There is, however, considerable difficulty in certain cases whether a bird should be assigned to one group or another, and there is the decided objection that nearly allied forms are often widely sundered. More serious is the absence of any attempt on the part of the author to lift his readers above the level of mere collectors and observers, and to point out that the bird-fauna of the extensive tract under consideration contains elements pertaining to more than one zoological province. There is, for example, no indication that the one species of humming-bird found

in Eastern North America is essentially an immigrant from the South American fauna, and as strange to the Holarctic fauna as is the armadillo met with in Texas. The inclusion, too, of rare stragglers from Europe is certainly a mistake in a work of this nature; the most glaring instance being the introduction of the common kestrel, on the strength of a single specimen obtained in Massachusetts.

Another point open to criticism is the popular nomenclature of certain species. In the review of another work on American birds, attention has been already drawn in this journal to the inconvenience arising from the application of the names of well-known European birds to totally different American species, but this sinks into insignificance when compared with the practice of using a name belonging to a South American bird for a North American songster. In the Argentine and other parts of South America there exists a well-known group of *Dendrocolaptidae*, universally termed oven-birds (*Furnarius*), and it is accordingly in the highest degree inconvenient to employ the same title for a North American representative of the *Mniotiltidae*, especially when the bird in question (*Sayornis auropigra*) has the alternative name of golden-crowned thrush.

The descriptions of the various birds referred to seem for the most part well adapted for popular use, and the author's practice of frequently italicising one or more of the leading distinctions is decidedly worthy of commendation. We are also fully in accord with the author when he says that the meaning of colour descriptions can only be fully grasped by observation and experience, seeing that no two describers will ever designate one particular shade of red or other colour by precisely the same term. And if this be true of colour, still more is it so with regard to song, which Mr. Scott regards as inexpressible, either in words or by instruments.

With regard to the numerous photogravures with which the volume is illustrated, the author states that these have been prepared under his own immediate supervision. "Some," he writes, "are taken from live birds, others from dead ones, some are from stuffed birds, others from prepared skins. All are faithful and accurate pictures, just what the camera presents, with its keen interpretation." This is candid, and enables the reader without much difficulty to arrive at the nature of the subjects for the different photographs. Although by no means all on the same level, these latter are on the whole of a high standard of excellence, and serve to render the volume attractive not only to students of bird-life, but to lovers of nature in general. Among the most successful effects, mention may be made of the purple finch (p. 49), the screech-owl (p. 72), and the nest of the flicker (p. 176). Interspersed in the text are a number of photographs of dead birds, for the most part lying on their backs, with their feet in the air. Although these may be valuable as aids to the identification of the species, to our own mind they convey a somewhat melancholy impression, especially in the case of song-birds, which should be the incarnation of life and joy.

Limitations of space have probably been the reason that the author's descriptions of habits are for the most part brief; and this is the more to be regretted seeing

that he writes in a manner well calculated to attract the attention of his readers. Apparently he is one of those who think that everything has been arranged for the best in this best of possible worlds. For example, after stating that, owing to its parasitic habits, maledictions are poured down on the devoted head of the coward by all, he proceeds as follows —

"This may be to an extent warranted, but the fact that the great laws of nature have developed a necessity for such a bird seems to bespeak for it at least patient and careful consideration. There are few, if any, unmixed evils allowed to survive in the great struggle for existence, but the good results are not always patent even to the most careful student."

With the exception of undue weight, owing to the employment of heavily clayed paper, the style in which the book is produced is worthy of all praise, and renders it an attractive addition to the library or drawing-room table. Probably its circulation in this country will be somewhat limited; but in the land of its birth the volume should command an extensive sale, which we may hope will be sufficient to induce the author to favour the public with its promised companion. R. L.

THE CASE AGAINST VACCINATION

A Century of Vaccination, and what it teaches. By W. Scott Tebb, M.A., M.D. (Cantab.), D.P.H. (London Swan Sonnenschein and Co., Ltd., 1898.)

DR. TEBB says that on the assumption that the father of a family ought to be able to form a judgment upon vaccination, a practice established and enforced by law, he will attempt in the work before us to discuss a great question in an unbiased fashion. In this attempt he is not altogether successful. After stating that he does not reject, or even attack the belief that a certain degree of immunity in the case of certain diseases is conferred by a first attack, he goes on to draw a distinction between the immunity conferred by small-pox and that conferred by cow-pox. He appears to beg the whole question by accepting, as conclusively proved by Dr. Creighton and Prof. Crookshank, the proposition that cow-pox is a disease radically different from that from which it is said to protect. This point is one, however, that no amount of asseveration can settle, and most people prefer to be guided by the results of recent experiments rather than by polemical statement.

In a piece of rather clever special pleading, Dr. Tebb makes a statement that

"should there be an epidemic in a locality where 85 per cent. of the population are vaccinated, it is obvious that the 95 per cent. of the population should escape the epidemic, assuming, as before indicated, that a maximum of 5 per cent. attacked by it will largely coincide with the 85 per cent. vaccinated, and thus vaccination gains credit, but it will be objected if the 5 per cent. attacked coincide, in however small a degree, with the 15 per cent. unvaccinated, this is strong testimony to the risk of being unvaccinated, and so no doubt it would be but for the fact that in localities where the vaccination law is vigorously carried out the unvaccinated as a class will be found to consist largely of the outcasts of society, nomads whom the law has failed to reach, and of weakly children who, on account of their health, have been excused the operation. This class, therefore, is likely to

furnish a disproportionate number of the victims of the epidemic; and thus again the prophylactic acquires reputation."

This, as we have said, is nothing more than special pleading, especially when Dr. Tebb attributes bias to those who have to do with the collection and arrangement of the statistics on which vaccination arguments are based. It is for this reason that we refer to the bias imported into this controversy by Dr. Tebb at the very outset. Further, one cannot help feeling that the imputation by the author of the term "public endowment practice" indicates a state of mind not conducive to the calm and dispassionate consideration of this very important question. For example, he speaks of a "body of officials ostensibly paid to promote the practice of vaccination, but also, partly at least, paid to vindicate it theoretically and to explain away its failures and its accompanying disasters." "Take away," he says, "first the compulsory law, and then take away (if vested interest is not too strong for you) the endowment of the practice, and when this has been done medical men will find themselves, for the first time since 1803, free to discuss the vaccination question as a scientific one on its own merits." This is imputing motives with a vengeance—motives of a most sordid character. When an author holds such an opinion, no question with which he deals can be reasonably or profitably discussed.

After going carefully over "A Century of Vaccination," and granting the absolute accuracy of every stated fact put forward in this work, we are compelled (and we believe that most people will agree with us on this point) to come to the conclusion that Dr. Scott Tebb, if he started in an absolutely unfettered condition of mind, has been very easily brought to his present position, and that his marshalling of facts has been of such a one-sided character, that he has been enabled to argue far too readily from the special and the isolated to the general. He has placed his isolated facts in one scale and has left out the accumulated knowledge of all kinds that appears to tell against his theory, and has then struck a balance, of course in favour of the argument for which he is contending. So convinced are we on this point, that we are confident that it would be a safe plan for those who believe in the efficacy of vaccination to place this work in the hands of most anti-vaccinators, and ask them to read it on the condition that they would also read the context of many of the quoted passages, we believe such a course could have but one result. It may be stated generally that in the summary and conclusion Dr. Scott Tebb entirely misses or ignores the position taken up by those who are in favour of vaccination. He mixes up the risk to the individual with the risk to the community—a good system of vaccination with a system carelessly carried out, he bases the statement that it is valueless entirely on the assumption that cow-pox and small-pox are in no way generically related, and, putting aside the question of immunity as the result of an attack of small-pox, he contends that cow-pox is a specifically different disease, and can therefore exert no protective influence against small-pox. However, as we have already stated, those who read Dr. Tebb's book will, unless we are much mistaken, remain vaccinators, whilst those who are already convinced in the opposite direction may be brought to consider the

question from another standpoint, if they will only read a little wider into the context than the author allows them to do in his work. We do not wish to impugn Dr Tebb's absolute honesty in this matter; we are only astonished that, with the materials at his disposal, much of which he has evidently read very carefully, he has arrived at the position indicated in this work

OUR BOOK SHELF

The Heat Efficiency of Steam Boilers Land, Marine, and Locomotive With tests and experiments on different types, heating value of fuels, analyses of gases, evaporation, and suggestions for testing boilers By Bryan Donkin, M Inst C E. Pp xvi + 311. (London: Charles Griffin and Co, Ltd, 1898)

THE main value of this book will undoubtedly lie in the tables, which fill about 100 of its pages, and give in an admirably complete form the results of no less than 405 tests of the efficiency of steam boilers of almost every type. The labour of collecting the material must have been great, and the author has selected with judgment the information needed, practically everything wanted is to be found in the twenty-six columns of the tables, and no useless matter has been incorporated. The only addition which might have been made with advantage is the temperature of the feed-water, especially in those cases where no economiser was in use. Useful summary tables are given on pp 116, 117 and 118, and in chapter xii the author discusses the general conclusions to be drawn from these trials, but without coming to any definite decision. As pointed out in the book, the wide variations in the efficiency of the same type of boiler when worked under different conditions makes it impossible to lay down any general laws, though the graphic representation on p 223 of the relationship between efficiency and rates of evaporation per square foot of heating surface per hour, is of much value, and should be of use to the designer.

In reference to the calculation of the heating value of coal by Dulong's formula, there can be no doubt that it gives results which are too small when compared with calorimeter tests, the figures will be found, however, to agree much better when in the calculation no deduction is made from the hydrogen for the portion assumed, apparently without reason, to be chemically united with the oxygen. A valuable chapter is that dealing with the transmission of heat through boiler plates, because Blechynden's and Durston's recent experiments on this important question are given in a very clear and concise fashion for reference.

The author hardly devotes enough space to the description of the instruments for analysing furnace gases and their use, and those unfamiliar with the appliances and their working will find it difficult to teach themselves much by merely reading these paragraphs; they might well have been amplified since, as the author points out, the accurate analysis of the gases is the most important, and certainly the most difficult, point in boiler testing.

In addition to dealing with boiler testing, the author describes many of the important accessories which have been introduced of recent years to reduce the cost of steam generation, such as mechanical stokers, patent grates, economisers, superheaters, &c., and much information as to the value of these devices will be found in the chapters devoted to them. The author may be congratulated, for his book is one which cannot fail to be a standard reference work to all engaged either in boiler construction or in steam generation. An admirable little bibliography finishes up a series of useful appendices which give full directions for carrying out boiler trials.

H. B.

A Text-book of Geodetic Astronomy By John F Hayford, C E. (New York: John Wiley and Sons London: Chapman and Hall, Ltd, 1898)

WE must confess that the examination of this book has proved a little disappointing. This disappointment was probably inevitable from the circumstances in which the book has been produced, and the object which it is intended to serve. It appears that in the Cornell University the students of civil engineering devote five hours a week during one term to the study of astronomy. In this short space of time it is found impossible to master the contents of such a book as Chauvenet or other recognised standard work, and to meet this difficulty this book is put forward, not on the ground that it contains as much information as a student should acquire, but as much as he can acquire in the short time at his disposal. The sacrifice of thoroughness and completeness to the necessities of a particular University course can neither meet with general approval nor result in the production of a satisfactory treatise.

The title scarcely describes the character or the purpose of the book, which is mainly devoted to the practical determination of stellar positions by means of portable instruments. Considered from this point of view, and as showing in detail the methods employed in the United States Coast and Geodetic service, the book is not without its interest. On its practical side, we can conceive that it would be of use to those who have carefully read the theoretical, but to regard it as an efficient substitute for Chauvenet, would be to make a great mistake in the training of the student. The mathematical processes are, the author tells us, purposely omitted, but it would seem that other things besides mathematics have been omitted, which one would expect to meet in a work of this description. We should hope to find here a discussion of the figure of the earth, and, as a practical matter of great importance, a description of the method of measuring a base line. These matters are passed over entirely, and other important, but minute, results of observation get a very bare mention. For instance, to the variation of latitude only a page and a half is devoted. Pendulum experiments and their results do not come within the scope of the book. On the other hand, we get a fairly good account of the sextant, the transit, the zenith telescope, of the determination of the errors of these instruments, and the method of combination of observations. Some astronomical tables are added which are likely to prove useful.

Machine Drawing Book 2. Part 1. Machine Tools. By Thomas Jones, M I Mech E, and T Gilbert Jones, M Sc. (Vic.) (London and Manchester: John Heywood, 1898)

THIS work is intended "for the use of engineering students in science and technical schools and colleges." It contains twenty-five lithographed plates, upon which are represented the elevations and details of important machine tools in actual use by expert engineers at the present time. The plates include drawings of a drilling machine, planing machine, stroke slotting machine, stroke shaping machine, and forms of gearing. The complete drawings of the three first-named machines are coloured, and all of them are well executed. With the explanatory text the engineering student will find the work instructive and of real assistance.

A Student of Nature. By R. Menzies Fergusson, M A. Pp. 246. (London: Alexander Gardner, 1898.)

THE late Rev Donald Fergusson was many-sided in his pursuits, and among his pleasures was the study of natural history. One of the sections of the present volume contains the papers written by him on rural life and scenes, and they show that he was filled with "deep feeling" by nature and its wild life, but neglected the minute examination of natural objects essential to scientific study.

Undercurrents in the Strait of Bab-el-Mandeb

AN interesting observation has recently been made by one of H.M. surveying vessels, and I forward the Preface to the account of the details published by the Hydrographic Department, which contains the principal facts, and also the Analysis of the observations, both of which may be of interest to some of your readers.

W. J. L. WHARION
Hydrographic Department, Admiralty, Whitehall,
London, S.W., September 27.

UNDERCURRENTS IN THE STRAIT OF BAB EL MANDER

It has long been known that in the Bosphorus and Dardanelles when the surface water sets strongly from the Black Sea to the Mediterranean, the lower strata of the water for a certain height from the bottom sets strongly in the opposite direction.

While in this instance it is probable that the many large rivers which discharge their waters into the Black Sea have a

originally devised by Lieutenant Pillsbury, U.S.N., and considerably altered after a series of experiments by Captain Osborne Moore in the English and Færoe Channels, seemed to offer a chance of more success.

Lieutenant and Commander Gedge, commanding H.M. surveying ship *Stork*, was therefore directed to endeavour to get further observations in Bab-el-Mandeb by means of this instrument, and has admirably and most successfully carried them out.

On January 19, 1898, the *Stork* was anchored in 118 fathoms about seven miles S.W. by W. from Veron Island, and remained constantly observing, during daylight, for four days, when the parting of the cable brought the series to a close. Had not the wind been unusually light, varying from force 3 to 6, it is probable that the observations could not have been continued so long.

The observations are appended (in publication quoted), but the broad result may be briefly stated.

There was a permanent current on the surface setting into the Red Sea of about 1½ knots per hour.

There was at 105 fathoms depth a permanent current setting outwards of probably the same velocity.

The tidal stream was about 1½ knots at its maximum, and flowed for about twelve hours each way, as might be expected from the fact that in this locality there is practically only one tide in the day.

Analysis of Tidal Streams observed in the Large Strait of Bab-el-Mandeb by H.M.S. *Stork* in January 1898

share in producing the surface current, the observations by which the undercurrent was revealed appeared to plainly indicate that the surface drift, caused by the generally prevailing N.E. wind heaping the water up in the south western part of the Black Sea, was the main factor.

The somewhat similar conditions which occur in the strait of Bab-el-Mandeb offered another opportunity of observation on this interesting form of oceanic circulation, and for many years such observations have been a desideratum.

In this strait for nearly half the year a more or less strong easterly wind prevails, driving much water before it into the Red Sea, and, great as is the evaporation from the surface of that sea, which must be made up wholly by an inflow of water through the strait of Bab-el-Mandeb, it appeared on the whole probable that during this season the phenomenon of the Dardanelles would be repeated.

The observation is, however, difficult. The water is deep, over 100 fathoms; the sea generally heavy, there is a tidal current to complicate matters; and it seemed doubtful whether the somewhat crude apparatus which served to unravel the movement of the lower strata in the shallower and smoother Dardanelles would give good results in this locality.

Nevertheless, Captain W. Osborne Moore was directed to attempt it in H.M.S. *Penguin* in 1890, but the results, while showing that the under strata were not running with the surface, were too ambiguous to afford much definite information.

The possession, however, of a deep-sea current meter,

This tidal stream prevails to the bottom, with variations of strength.

Somewhere about 75 fathoms is the dividing line between the two permanent currents, but it would require a longer series of observations to determine this point with any precision.

Fourier's Series

In all expositions of Fourier's series which have come to my notice, it is expressly stated that the series can represent a discontinuous function.

The idea that a real discontinuity can replace a sum of continuous curves is so utterly at variance with the physicist's notions of quantity, that it seems to me to be worth while giving a very elementary statement of the problem in such simple form that the mathematicians can at once point to the inconsistency if any there be.

Consider the series

$$y = 2 \left[\sin x - \frac{1}{2} \sin 2x + \frac{1}{3} \sin 3x - \dots \right]$$

In the language of the text-books (Byerly's *Series and Spherical Harmonics*) this series "coincides with $y = x$ from $x = -\pi$ to $x = \pi$."

Moreover the series in addition to the continuous portions of the locus . . . gives the isolated points $(-\pi, 0)$, $(\pi, 0)$, $(3\pi, 0)$, &c.

If for x in the given series we substitute $\pi + \epsilon$ we have, omitting the factor 2,

$$-y = \sin \epsilon + \frac{1}{2} \sin 2\epsilon + \frac{1}{4} \sin 3\epsilon + \dots + \frac{1}{n} \sin n\epsilon + \dots$$

This series increases with n until $n\epsilon = \pi$. Suppose, therefore, $\epsilon = \frac{\pi}{n}$, where $\frac{1}{n}$ is a small fraction. The series will now be nearly equal to $n\epsilon = \pi$, a finite quantity even if $n = \infty$.

Hence the value of y in the immediate vicinity of $x = \pi$ is not an isolated point $y = 0$, but a straight line $-y = \pi x$.

The same result is obtained by differentiation, which gives

$$\frac{dy}{dx} = \cos x - \cos 2x + \cos 3x - \dots$$

putting $x = \pi + \epsilon$ this becomes

$$-\frac{dy}{dx} = \cos \epsilon + \cos 2\epsilon + \cos 3\epsilon + \dots + \cos n\epsilon + \dots$$

which is nearly equal to n for values of $n\epsilon$ less than π .

It is difficult to see the meaning of the tangent if y were an isolated point.

Helium in the Atmosphere.

C. FRUHNANDER and H. Kayser have independently claimed to have found helium in the atmosphere. On examination of some photographs of the spectrum of neon I have identified six of the principal lines of helium, which thus establishes beyond question the presence of this gas in the air. The amount present in the neon is, of course, impossible to estimate, but the green line (wave-length 5016) is the brightest, as would be expected from the low pressure of the helium in the neon.

E. C. C. BALY

University College, London, Gower Street, W.C.,
September 28.

THE discovery of helium lines in the spectrum of neon, by Mr. E. C. C. Baly, will necessitate a modification of the views we have expressed in our communication to the British Association at Bristol. We there estimated the density of neon at 96, allowing for the presence of a certain proportion of argon unavoidably left in the neon. As it contains helium, however, this is probably an under-estimate. It is unfortunately not possible to form any estimate of the amount of helium mixed with the neon from the relative intensity of spectrum lines, as has been already shown by Dr. Collie and one of us; we do not despair, however, of removing a large part, if not all of this helium, by taking advantage of the greater solubility of neon than helium in liquid oxygen.

The presence of helium, however, in no way alters our view as to the position of neon in the periodic table. The number 96 implies an atomic weight of 19.2, and a somewhat higher atomic weight would even better suit a position between fluorine, 19, and sodium, 23.

Chance or Vitalism?

I AM glad to see that Prof. Karl Pearson has called attention to Prof. Japp's address at Bristol. Only that one does not like to criticise adversely a presidential address, I would at the time have pointed out the weakness in the argument that Prof. Pearson criticises. He does not go nearly so far in this criticism as the circumstances warrant. It is conceded that right- and left-handed crystals of quite sensible size are produced sufficiently separated to be seen and handled as separate crystals. Now assuming, what there is every reason otherwise to think quite probable, that life started from some few centres, the chances are, not that it was equally divided between right- and left-handed forms, but that one or other of these forms preponderated. In fact, if life started from a single centre, it *must* have been either right- or left-handed. Hence the fact adduced only shows, what was otherwise very probable, that life started from a small number of origins, probably only one.

Another reason for either a right- or left-handed structure in living organisms on the earth, and one which diminishes the force of the foregoing argument for a small number of origins, is that it probably started either in the northern or in the southern hemisphere, and in either case the rotation of the sun in the heavens may be a sufficient cause for a right- or left-handed structure in an organism growing under its influence.

GEO. FRAS. FITZGERALD.

Trinity College, Dublin, September 27.

IN his presidential address to Section B of the British Association, Prof. Japp argues the necessity of supposing a "directive force," or intelligence, to have guided the formation of the first asymmetric substance "Vitalism," which at one time was supposed to regulate the physiology and even the mechanics of organised beings, has passed more and more from the foreground, till, in the vision of some it remains only as a point in the vast distance of time at the origin of life. Is it to disappear altogether?

A sensible quantity of a mixture of enantiomorphs contains an enormous number of molecules. Chance determines the relative proportion present of right- and left-handed forms. Each molecule, having resulted from the action of symmetric forces, has an even chance of being of one or the other. Hence, the improbability of there being present a great preponderance of one form over the other is so great, that it is inconceivable that an optically active solution could result. To the above contention of Prof. Japp, the reply is made by Prof. Karl Pearson, in NATURE of September 22, that a chance result, however improbable, will occur, if sufficient opportunity be allowed. He postulates the vast ages of the earth's history. May we not, however, invoke chance to deal with masses instead of molecules, and thus perhaps substitute weeks for ages?

Let us consider a solution, in which the numbers of right- and left-handed molecules are very approximately equal, and which is consequently optically inactive. In the slow evaporation of the solvent, the right- and left-handed nuclei, about which the substance crystallises, will *most probably* be evenly distributed. Their number will be extremely small in comparison with that of the molecules, and, as chance determines their distribution, it is not so highly improbable—it is at least conceivable—that the crystals will be unevenly grouped. Suppose such to take place and a partial re-solution, roughly in the lines of the distribution of the two varieties of crystals—a not very improbable event—and we have an optically active solution. Chance has here acted the part played by organised matter in the person of M. Pasteur, by selecting and rejecting the oppositely formed crystals.

Is it yet possible to deny that the first ancestor of lavo-rotatory protein could have been built up from an asymmetric substance, separated in some such way as the above, by the play of chance upon the natural working of symmetric forces?

The Moon's Course

MAY I refer Sir S. Wilks to the simple and beautifully written autobiography of James Ferguson, F.R.S., self-taught mechanic and astronomer? I will quote a passage

"Sixteen afterwards" (the previous date was 1743) "I appeared to me, that although the moon goes round the earth, and that the sun is far on the outside of the moon's orbit—yet the moon's motion must be in a line—that is, always concave toward the sun—and upon making a delineation representing her absolute path in the heavens—I found it to be really so. I then made a simple machine for delineating both her path, and the earth's, on a long paper laid on the floor. I carried the machine and the delineation to the late Martin Folkes, Esquire, President of the Royal Society, on a Thursday afternoon. He expressed great satisfaction at seeing it, as it was a new discovery, and took me that evening to the Royal Society, where I showed the delineation and the method of doing it. When the business of the Society was over, one of the members desired me to dine with him the next Saturday at Hackney, telling me that his name was Ellicott, and that he was a watchmaker. I accordingly went and was kindly received by Mr. Ellicott, who then showed me the very same kind of delineation and part of the

of fuchsin, and had been experimentally investigated with great power by Kundt.¹

Sellmeier himself somewhat marred² the physical value of his mathematical work by suggesting a distinction between refractive and absorptive molecules ("refractive und absorptive theilchen"), and by seeming to confine the application of his formula to cases in which the longest of the molecular periods is small in comparison with the period of the light. But the splendid value of his formula for physical science has been quite wonderfully proved by Rubens (who, however, inadvertently quotes³ it as if due to Ketteler). Fourteen years ago Langley⁴ had measured the refractivity of rock-salt for light and radiant heat of wave-lengths (in air or ether) from $\frac{1}{43}$ of a mikron to $\frac{1}{53}$ mikrons (the mikron being 10^{-6} of a metre, or 10^{-4} of a centimetre), and without measuring refractivities further, had measured wave-lengths as great as 15 mikrons in radiant heat. Within the last six years measurements of refractivity by Rubens, Paschen, and others, agreeing in a practically perfect way with Langley's through his range, have given us very accurate knowledge of the refractivity of rock-salt and of sylvin (chloride of potassium) through the enormous range of from $\frac{1}{4}$ of a mikron to 23 mikrons.

Rubens began by using empirical and partly theoretical formulas which had been suggested by various theoretical and experimental writers, and obtained fairly accurate representations of the refractivities of flint-glass, quartz, fluor spar, sylvin, and rock salt through ranges of wave-lengths from $\frac{1}{4}$ to nearly 12 mikrons.⁵ Two years later, further experiments extending the measure of refractivities of sylvin and rock-salt to radiant heat of wave-lengths up to 23 mikrons, showed deviations from the best of the previous empirical formulas increasing largely with increasing wave-lengths. Rubens then fell back⁶ on the simple unmodified Sellmeier formula, and found by it a practically perfect expression of the refractivities of those substances from $\frac{1}{434}$ to 23 mikrons.

And now for the splendid and really wonderful confirmation of the dynamical theory. One year later a paper by Rubens and Aschkinass⁷ describes experiments proving that radiant heat after five successive reflections from approximately parallel surfaces of rock-salt and again of sylvin, of mean wave-length 51.2 and 61.1 mikrons respectively. The formula which Rubens had given in February 1897, as deduced solely from refractivities measured for wave-lengths of less than 23 mikrons, made μ^2 negative for radiant heat of wave-lengths from 37 to 55 mikrons in the case of reflection from rock-salt, and of wave-lengths from 45 to 67 mikrons in the case of reflection from sylvin (μ^2 negative means that waves incident on the substance cannot enter it, but are totally reflected).

A FOURTH SPECIMEN OF "NOTORNIS MANTELLI," OWEN

NATURALISTS in New Zealand have this week been thrown into a great state of excitement by the capture of the fourth entire specimen of this very rare flightless Rail.

On August 8 I received a telegram informing me of the acquisition, and asking advice as to its preservation. Fortunately, a skilled taxidermist is attached to the Otago Museum, and I was able to arrange that the bird

should be sent to that institution—it arrived two days later, and its remains are now in my care.

The last specimen of *Notornis* was captured twenty years ago, and it was almost universally considered by Maories, as well as by whites, to be extinct; hence the interest that attaches to the present specimen.

It may not be uninteresting to naturalists at home to be reminded of some facts in the history of *Notornis* as recorded in Buller's "Birds of New Zealand." The name was originally bestowed by Owen on some fossil bones discovered in the North Island, New Zealand.

Some years later (1849), Mr W. Mantell was able to secure a freshly killed specimen, taken in the south-west of the Middle Island (the southern of the two main islands of New Zealand). This bird, the skin of which is in the British Museum, was declared by competent ornithologists at home to be identical with the fossil form. The second specimen was killed by Maories in 1851, and its remains are also in the National Collection. The third specimen was obtained nearly thirty years later, in 1879, and was purchased for the Dresden Museum. (From an examination of the bones Dr A. B. Meyer declared it to be distinct from the fossil form, and named it *N. hochstetteri*.) These three specimens were killed at three spots about 100 miles apart, in very rugged country. Later, an incomplete skeleton was discovered, which is at present in the Otago Museum.

The bird recently killed is thus the fourth specimen seen in the flesh, and its future fate is at present uncertain. It was killed by a dog in the bush adjoining Lake Te Anau, in the same district as the other three specimens.

I have examined and made sketches of its viscera, which, like all parts of the bird, are carefully preserved for the owner. The specimen is a young female, in excellent health and splendid plumage.

During the present month I have been fortunate enough to obtain, on deposit, an egg of the Moa—the third or fourth, I believe, in anything like a complete condition. Although the egg is much broken, one side remains practically complete, the pieces of the other side had fallen inwards, and are embedded in the sand within the shell. The egg was discovered in a sandy deposit, and when it reached me was partially enveloped in sand. This has been removed, as far as safety would permit, from the more complete side of the egg, and the whole was thoroughly soaked in weak gelatine to bind sand and shell together. The specimen closely agrees in size and shape with the cast, which is familiar in all museums, and alongside of which it is now on exhibition. As in the case of the eggs previously discovered, it was one of a pair, the other was unfortunately broken, on handling, by those concerned in its excavation.

W. BLANLAND BENHAM

Dunedin, August 14

A LIVING REPRESENTATIVE OF THE OLD GROUND SLOTHS

ALL naturalists will unite in congratulating Señor Florentino Ameghino on the remarkable discovery it has been his good fortune to make. It appears that several years ago he was informed by Ramon Lista—a traveller in Patagonia—of an encounter with a strange nocturnal beast, which, after being fired at and apparently hit, succeeded in escaping unharmed. It was described as like an Indian pangolin in size and form, but with the skin covered with greyish red hairs instead of scales; and from the rapidity with which it disappeared among the bushes, seemed to have been an animal of comparatively active habits. Till quite recently, nothing more had ever been heard of the strange creature seen by Lista in Santa Cruz, most of those to whom the story

¹ Kundt, *Phys. Ann.*, vol. 143, 143, 144, 145, 1871-72.

² *Phys. Ann.*, vol. 147, 1879, p. 293.

³ *Phil. Mag.*, vol. 52, 1864, p. 267. In the formula quoted by Rubens from Ketteler, substitute for μ the value of μ found by putting $r = 0$ in Sellmeier's formula, and Ketteler's formula becomes identical with Sellmeier's. Remark that Ketteler's " μ " is Sellmeier's " μ' " according to my notation in the text.

⁴ Langley, *Phil. Mag.*, 1886, and half-year.

⁵ Rubens, *Wied. Ann.*, vol. 53, 54, 1896-95.

⁶ Rubens, *Wied. Ann.*, vol. 60, 1896-97, p. 454.

⁷ Rubens and Aschkinass, *Wied. Ann.*, vol. 64, 1898.

was narrated receiving it with more or less marked incrudility.

A short time ago, however, Señor Ameghino was shown a number of fresh ossicles from Patagonia, of somewhat smaller size than coffee-berries, which he at once recognised as comparable with the somewhat larger bones commonly found in association with the remains of certain species of *Myiodon* from the pampean deposits of the Argentine, and which have always been regarded as indicating the presence of a dermal armour in those animals. These ossicles, it appears, were extracted from a badly preserved body-skin, which seems to have been exposed for some time to the action of the weather, and consequently to have become considerably discoloured. In thickness this skin measured about two centimetres, and its hardness and toughness were such that it could be cut only with a chisel or hatchet. In its deeper layer were embedded the ossicles, and in those places where it was least damaged it was covered with coarse reddish grey hair, from 4 to 5 centimetres in thickness.

The skin evidently belonged to an animal hitherto unknown to science, and, in spite of the absence of the limbs, the presence of the ossicles seems to afford decisive evidence that it indicates an existing small representative of the ground sloths, more or less intimately related to the typical group of the genus *Myiodon*. Moreover, in the colour of the hair it agrees with Lista's description of his unknown animal, which he confidently asserted to be an *Edeutatus*. Señor Ameghino seems, therefore, to be fully justified in regarding the two specimens as pertaining to one and the same species, and that species to be a living representative of the *Megalotheriidae*, hitherto known only in the fossil. For this animal the name of *Neomyiodon listai* is proposed, but the specific title should be amended to *listae*.

Dermal ossicles are only known to be developed in certain species of *Myiodon* and *Glossotherium*, and have not been detected among the remains of the smaller ground-sloths characteristic of the Patagonian formations. The presumption accordingly is that the new animal is more or less closely allied to these genera, from which, indeed, its right to distinction has yet to be demonstrated.

This animal is doubtless nocturnal, and also of rare occurrence, and some time may therefore probably elapse before a perfect specimen is obtained. Till that event happens naturalists must be content with the fact that a survivor of the old ground-sloths exists in the interior of Patagonia.

REPORT ON A NATIONAL PHYSICAL LABORATORY

THE Committee appointed in August, 1897, to consider the desirability of establishing a National Physical Laboratory have issued their report. The Committee consisted of Lord Rayleigh, F.R.S. (chairman), Sir Courtenay Boyle, K.C.B., Sir Andrew Noble, K.C.B., F.R.S., Sir John Wolfe Barry, K.C.B., F.R.S., Prof. W. C. Roberts-Austen, C.B., F.R.S., Mr. Robert Chalmers, Prof. A. W. Rucker, F.R.S., Mr. Alexander Siemens, and Dr. T. E. Thorpe, F.R.S. The questions referred to them were as follows:—

"To consider and report upon the desirability of establishing a National Physical Laboratory for the testing and verification of instruments for physical investigation; for the construction and preservation of standards of measurement; and for the systematic determination of physical constants and numerical data useful for scientific and industrial purposes—and to report whether the work of such an institution, if established, could be associated with any testing or standardising work, already performed wholly or partly at the public cost."

The following are extracts from the report of the Committee:—

In general, the committee are of opinion that the appliances and facilities of the Standards Office and of the Electrical Standardising Laboratory are fairly adequate for the performance of their statutory duties. They understand, however, that on account of the want of means for the chemical analysis of the materials used in the construction of standards, those offices would find some difficulty, without extraneous assistance, with regard to any new standards that might be required.

They further desire to point out that many physical constants and data and numerical expressions are necessarily used in connection with standards and the standardising of instruments. Some of the data now in use at the Standards Office are known to require correction, and in the case of others further investigations appear to be desirable. There is, however, no legal obligation on the Board of Trade to establish new data and numerical expressions, and, in consequence of the smallness of the staff of the office the work of the Department is limited to that which is strictly enjoined by the Acts of Parliament. The Department is at the present time chiefly dependent for more exact knowledge on such investigations as may be undertaken at the Bureau International des Poids et Mesures at Paris, or by foreign institutions similar to that contemplated in this country.

There is much evidence that further facilities are needed by the public for standardising and verifying of instruments, both for scientific and commercial use, and also that it would be of great benefit to trade if means were provided for the public testing of the quality of certain classes of materials. In particular the committee desire to draw attention to the evidence which has been laid before them as to the difficulties arising in certain Government departments in their dealings with contractors and others which might be overcome by the establishment of an independent testing authority. It would neither be necessary nor desirable to compete with or interfere with the testing of materials of various kinds as now carried out in private or other laboratories; but there are many special and important tests and investigations into the strength and behaviour of materials which might be conducted with great advantage at a laboratory such as is contemplated in the reference. As illustrations we may mention investigations into the behaviour of metals and other substances under continuous or alternating stresses, which investigations are not, so far as we know, conducted at the present time at any testing institution in this country, and which could only be undertaken with satisfactory and authoritative results at a public laboratory.

For many years the testing of certain instruments has been carried out at the Kew Observatory under the direction of the Kew Observatory Committee of the Royal Society. There is much evidence that the existence of these tests has been of great benefit to both science and industry. On the one hand it enables the maker to give, or the purchaser to obtain, an independent and trustworthy statement as to the quality of the instrument. On the other hand, the existence of the tests has led in many cases to a marked improvement of the instruments, and similar results may be anticipated by an extension of these facilities to other branches of industry.

The Kew Observatory is a Government building leased to the Royal Society at a nominal rent, situate in the Old Deer Park, Richmond, which is Crown property. The Institution has no endowment, the Gassiot Fund producing about 470*l* per annum. From the Meteorological Office it receives annually 400*l*, part of which is the ordinary grant made to a first-class meteorological station, the remainder being for scientific assistance. The fees received for the verification and testing of instruments amount to about 200*l*. per annum. The Institution is self-supporting, and has usually a small annual balance which is devoted to scientific investigation and to the extension of the work, including the erection of new buildings, when required. The funds at the disposal of the Observatory Committee are, however, quite inadequate to any considerable extension of its operations. The work done with restricted means has been very useful. The total number of instruments annually verified, or tested is about 22,000. Among these are included watches, thermometers, sextants, barometers and other apparatus used for scientific or industrial purposes. Evidence was given of the beneficial effect which Kew has exerted on the watchmaking trade, and it is noteworthy that this is due to the introduction of tests for which there was little or no previous demand on the

part of the trade, though there is now keen competition among the best makers to secure a high place in the report which is annually issued.

In the opinion of the committee the principles which underlie the proposal for the establishment of a national physical laboratory have been tested on a comparatively small scale at the Kew Observatory with the most satisfactory results.

In addition to the physical constants and numerical data needed in connection with standards, there are numerous facts, a knowledge of which would be of great value to science and industry. The determination of such data usually involves an investigation as to the method of making the determination, and a considerable expenditure of skilled labour in carrying out the determination. The committee are of opinion that, although the former part of this work will in general be initiated by individual experimenters of great skill and originality, it may in special cases be usefully undertaken by a public body. It is rather to the improvement in the details of the method of making the determination that they think that the work of a public institution will for the most part be directed. This cannot usually be carried out by private investigators on account of the expense and the length of time over which the experiments must extend. The scientific reputation to be gained is often incommensurate with the labour involved; and even when the results are of industrial importance in many cases they cannot be protected by patents.

There is evidence that many questions of this nature are partially investigated for technical purposes by private persons, the results being not infrequently kept secret. More complete investigations carried out at a public institution and freely published would often be of great service to industry, and there is reason to believe that a large part of the cost of such work might be defrayed by the persons directly interested in the results.

One difficulty in connection with a scheme for the determination of constants and data arises from the fact that the number of subjects which might be pressed for investigation would be very large. The opinion was, however, generally expressed by the witnesses that a strong governing body would have no difficulty in selecting those branches of work which were the most important, and that it would be possible to confine the work of the proposed institution, if established, within moderate limits. Nearly all the witnesses, also, have expressed the opinion that those interested in industry as well as persons devoted to the study of pure science would be willing that the Royal Society should be ultimately responsible for the management of the proposed institution, provided that industry were adequately represented on the governing body, and that the choice of the members of that body, though nominated by the Council of the Royal Society, were not confined to Fellows of the Society.

After consideration of the evidence the committee have come to the conclusion that an institution should be established for standardising and verifying instruments, for testing materials, and for the determination of physical constants. Work useful both to science and industry could therein be performed for which no adequate provision is at present made, either in this country or at the Bureau International des Poids et Mesures. Such work could not, or, at all events, in all probability would not, be undertaken by individual workers, or by institutions primarily devoted to education. In the opinion of the committee the proposed institution should be established at the national expense on lines similar to, though not at present on the scale of, the Physikalisch-technische Reichsanstalt referred to above. The possibility of future extension should, however, be kept in view from the first.

To secure the efficient performance of the work, the committee are of opinion that the director of the institution should be a man of high scientific attainments, and should act under a governing body containing representatives of both science and industry. The director should not be called upon or allowed to undertake work not connected with the institution except with the consent of the governing body. He would require the support of an adequate staff. As regards locality, while it is desirable that the institution should be near London, it is necessary that the site be free from mechanical and electrical disturbance.

Among the most important questions considered by the committee was whether the proposed institution should be founded independently or should be a development of an existing institution. The duties of the Board of Trade, as custodian of certain

standards, are defined by statute, and the committee consider that it is undesirable to alter existing arrangements in this respect. They are of opinion that the proposed laboratory if established should be managed by a governing body constituted and appointed as hereinafter described, and should not be under the direct control of a Government department. They recommend that the Board of Trade, as custodian of the standards, should be placed in close connection with the said governing body.

The character of the work done at the Kew Observatory suggests that all that is really necessary might be attained by the development of that institution.

RECOMMENDATIONS

(1) That a public institution should be founded for standardising and verifying instruments, for testing materials, and for the determination of physical constants.

(2) That the institution should be established by extending the Kew Observatory in the Old Deer Park, Richmond, and that the scheme should include the improvement of the existing buildings, and the erection of new buildings at some distance from the present observatory.

(3) That the Royal Society should be invited to control the proposed institution, and to nominate a governing body, on which commercial interests should be represented, the choice of the members of such body not being confined to Fellows of the society.

(4) That the permanent secretary of the Board of Trade should be an *ex officio* member of the governing body, and that such body should be consulted by the Standards Office and the Electrical Standardising Department of the Board of Trade upon difficult questions that may arise from time to time or as to proposed modifications or developments.

NOTES

IN connection with the forthcoming conference upon an International Catalogue of Scientific Literature, a reception will be held at the Royal Society on Monday next, October 10. A dinner has been arranged by the President for Fellows of the Society and their friends who are interested in the subject of the Catalogue. It will take place at the Hôtel Métropole on Tuesday, October 11.

IN connection with the opening of the winter session of the Charing Cross Hospital Medical School on Monday, Prof. Rudolf Virchow, Director of the Berlin Pathological Institute, delivered the second of the Huxley lectures, his subject being "Recent Advances in Science, and their Bearing on Medicine and Surgery." Lord Lister, President of the Royal Society, occupied the chair, and a large number of members of the medical profession, and distinguished men of science were present. Prof. Virchow was most cordially received, and his address, printed in another part of this number, was followed with deep interest and attention.

MR. T. MELLARD READE informs us that the gypsum-boulder, weighing at least thirteen tons, found in the Boulder Clay of Great Crosby, and described in a previous number of NATURE (p. 132), has been presented to the District Council by Mr. Peters, and is now being moved from its original bed with the intention of erecting it in an open space in Liverpool Road, Great Crosby. A concrete platform has been prepared to receive the boulder. From the depth of the clay pit in which it lay, and its great weight and irregular form, the lifting, carriage and setting up of the boulder is one of considerable difficulty. The boulder will be protected with wrought-iron railings, and no doubt will prove an object of abiding interest to the neighbourhood and to geologists generally.

News has been received from Sitten (Canton Valais, Switzerland) that, on Monday, Captain Spelterini attempted the passage over the Alps in his balloon the *Vega*. He was accompanied by Prof. Helm, of Zurich, Dr. Mauer, director of

the Meteorological Bureau of Zürich, and Dr. Biederman, of Warsaw. The balloon contained 3268 cubic metres of gas, was nearly 200 feet in height, and was capable of carrying a weight of 110,000 kilos, or about 100 tons. Owing to unfavourable winds, the object of crossing the Alps was not attained. The balloon was carried in the wrong direction, and descended near Dijon in France. It reached a height of 6300 metres (20,670 feet).

ATTENTION has already been called to the fact that the executors of the late Baron von Mueller are collecting donations for the erecting upon his grave in the St. Kilda Cemetery, Melbourne, of a monument worthy of his fame. The monument is of grey granite, 23 feet in height, all highly polished, and will stand in the centre of a grave-plot 12 feet square, planted out with choice specimens of the Australian flora. We are now informed that the distinguished physiologist's supplemental volume of the "Flora Australiensis," upon which he had worked for years, and was preparing for the press at the time of his death, is to be published, together with two volumes on his administration as director of the Botanical Gardens, Melbourne, and embracing a biography and complete bibliography of his writings. The executors would feel favoured by the loan of any of his letters, or the communication of incidents in the Baron's life which friends may deem worthy of notice in the biography. Subscriptions and letters should be addressed "Rev W. Potter, 'Vonmueller,' Arnold Street, South Yarra, Melbourne, Australia."

WE regret to see the announcement of the death of Dr. J. L. T. Atchison, F.R.S., Brigade Surgeon (retired) of H.M. Bent Army, at the age of sixty three.

MR CHARLES F. BRUSCH has sent us a copy of a paper read by him before the American Association, on August 23, upon a new gas which he has detected in the atmosphere, and designated *Etherion*. We shall refer to this paper later, when we receive a spectroscopic demonstration of the existence of the new gas.

REFERRING to the death of M. Gabriel de Mortillet, the well known naturalist and anthropologist, the *Athenaeum* says that he was born in 1821 at Meylan, and educated at Chambéry and Paris. He left France in 1849 to escape imprisonment for a socialist publication, retiring to Savoy and Switzerland, where he arranged the museums of Annecy and Geneva. In 1856 he took scientific work in Italy; in 1864 he returned to Paris, and founded a periodical dealing with the primitive history of man. Henceforth he was occupied with organising congresses of prehistoric anthropology and archaeology. He was appointed curator of the Museum of Antiquities at St. Germain in 1868, and in 1875 he helped to found the Anthropological School at Paris, of which he was subsequently professor. Among his numerous books may be mentioned studies on the mollusca and geology of Savoy, the sign of the cross before Christianity, the potters of the Allobroges, and the prehistoric problem, while his work in learned periodicals was extensive.

AN exhibition of optical, mathematical, and scientific instruments is being held this week at the Mansion House, under the auspices of the Worshipful Company of Spectacle Makers, of which the Lord Mayor, Lieut.-Col. H. D. Davies, M.P., is the master. The formal opening ceremony was performed on Monday afternoon, under the presidency of the Lord Mayor. The exhibits comprise a number of ancient as well as modern scientific instruments. Mr. Lewis Evans (of King's Langley) displays, *inter alia*, seven astrolabes of the fourteenth to the seventeenth centuries, and a large number of portable sun dials from England, France, Germany, Italy, &c., showing the

development of the various types from the fifteenth century to the present time. Among other exhibits are the maximum and minimum thermometers used by Captain Ross in his various voyages round the world. The exhibition will be opened daily until Saturday inclusive, from two o'clock until nine, and a band will play every evening between five and eight o'clock.

THE announcement that *Natural Science* will cease at the close of the present year, will be received with regret by students of biological sciences in many parts of the world. The periodical has taken a high place among monthly reviews of scientific progress, and it will be widely missed. The cessation of the journal could be prevented if some one with sufficient time and means will come forward to take over the responsibilities of the present editor, who announces that "all stock, appurtenances, and goodwill" will be handed over to any scientific man who is prepared to take over the responsibility, and continue the journal as an independent organ. It is to be hoped that this opportunity will not be missed, and that the journal will not be permitted to drop out of existence.

AN interesting description of the electric railway on the Jungfrau, the first section of which was opened a few days ago, appears in the *Electrician* of September 23 and September 30, and from it we derive the following particulars.—The existing Wengern Alp Railway—a rack and pinion railway driven by steam locomotives—starts from Lauterbrunnen and ascends the Wengern Alp to the Little Scheidegg (an elevation of 6770 feet above sea-level) from whence it descends on the other side of the mountain to Grindelwald. The Jungfrau electric railway starts from the Little Scheidegg station of the Wengern Alp Railway and ascends the Jungfrau from the north side. There will be seven stations in all—namely, Little Scheidegg, Eiger Glacier (7610 feet), Eiger Wand (9220 feet), Esmeer (10,360 feet), Jungfraujoch (11,210 feet), Lift (13,430 feet), Summit of Jungfrau (13,670 feet). On the section of the line already opened there is only a distance of about 85 yards in tunnel, but from the Eiger Glacier onwards the railway will not touch the surface except at the stations. Almost immediately after leaving the Little Scheidegg station the gradient is 10 per cent., and this is increased to 20 per cent. at about half way to the Eiger Glacier station. From this station the gradient increases to the maximum of 25 per cent. and the line enters the long tunnel, about 450 yards of which has been driven up to the present. The remaining stations from Eiger Wand onwards will be built within the rock, and it is intended to fit them with restaurants and sleeping accommodation for those passengers who may wish to break the journey. From the Eiger Wand and Esmeer stations there will be no egress on to the mountain, and tourists will merely be able to enjoy the view from windows or balconies, but from the Jungfraujoch station it will be possible to go out on to the Jungfraumass and sledge over the perpetual snowfield to the Aletsch Glacier. The Jungfrau line is one of the most interesting applications of three phase transmission and distribution yet made. Water-power is made use of in the valley to generate three phase current at 7000 volts, and this is transmitted by means of overhead wires to transformer stations at the Little Scheidegg and the Eiger Glacier, where it is transformed to 500 volts by means of stationary transformers. Not only is electrical energy employed for traction purposes but also for lighting, heating, and for working the rock-drills used in the tunnels. The permanent way is built on the Strub rack system, and the locomotive truck geared to it carries two induction motors driven directly by the 500-volt three-phase current. The passenger cars, which are not pulled but pushed by the locomotive, are built for forty passengers. It is estimated that the railway will be completed by 1904.

It must now be accepted as one of the established facts of medicine that in almost all outbreaks of human plague rats are affected by a similar disease both before and during the epidemic. In an article upon the plague in Calcutta, Dr. F. G. Clemow points out in the *Lancet* that the evidence that the two diseases are the same is of exactly the same character as that which has established the identity of human and bovine tuberculosis, and there seems to be but little more reason for suspension of judgment in the one case than in the other. It may therefore be accepted that plague in man and plague in the rat are, as far as our present knowledge of the two diseases goes, one and the same disease. Evidence has also been published that the disease may attack other animals than the rat, such as dogs, pigs, pigeons, and domestic fowls. Some interesting evidence pointing to the possibility that rats were the means of introducing the plague infection into Calcutta, is given by Dr. Clemow. Before the date of the first recognised case of plague in man, intimation was received at the Health Office that a number of dead rats had been found in an office situated near the river, and a little later, other dead rats were found in a street close to and parallel with the river and in the warehouses of a shipping company near to the wharfs where ships unload. The occurrence seems to have been so unusual as to have at once attracted attention, and the premises were cleansed and disinfected. Some of these animals were examined at the municipal laboratory, and cultures of the plague bacillus were obtained from them. Right from the beginning of the outbreak dead rats in large numbers have been found in various parts of Calcutta, but more particularly in and near houses where cases of human plague had occurred.

In a report to the Administrator of St. Vincent, dated September 14, Mr. H. Powell, Curator of the Botanic Garden, Kingstown, gives some trustworthy meteorological statistics relating to the recent hurricane in that Colony. He states that the barometer gave timely indication of the coming storm, at 3h p.m. on September 6 the corrected reading was 29.926 inches, and at 3h p.m. on the 10th the mercury had fallen to 29.838 inches. This reading caused alarm, and cautionary notices were issued to various centres for dissemination. At 5h 55m. the next morning the reading was 29.724 inches, and the wind was blowing in fitful gusts from N and N.W. At 9h a.m., the usual hour for recording observations, the reading was 29.606 inches, and the wind was rushing from N. to W. At 10h a.m. the barometer had fallen to 29.539 inches, and the storm had commenced in earnest, the wind blowing from N.N.E. and W., and increased in such force that at 11h a.m. that the largest trees were uprooted. By 11h 40m. the barometer had fallen to 28.509 inches, after which time there was almost a dead calm for about three-quarters of an hour. The rain gauge was emptied, and 4.94 inches were found to have fallen between 9h a.m. and noon. At about 12h 25m p.m. the wind suddenly commenced to blow from S., and increased in force every minute. Trees and houses which had withstood the first part of the hurricane were now hurled to the ground, the wind force far exceeding that of the forenoon; this continued till about 2h 30m. p.m., when the wind slackened considerably. During the lull between 11h 40m. and 12h 30m. the barometer remained steady at 28.509 inches, and then commenced to rise slowly, and afterwards rose as rapidly as it had previously fallen; at 3h p.m., the usual recording hour, it had risen to 29.533 inches. Up to this time the rain had fallen in torrents, but the gauge had been overturned. The total rainfall measured was over 9 inches in the twenty-four hours, and it was estimated that another 5 inches was lost by the upsetting of the gauge. Distant thunder and lightning were recorded at intervals during the morning and afternoon. Persons living in St. Vincent who

remember the "Great Hurricane" of August 11, 1831, state that the recent one was in every way far more destructive.

By a decree dated August 30 last, the Belgian Government has separated the astronomical from the meteorological service (see *NATURE*, vol. lvi. p. 183), each of these departments being placed under a responsible scientific director, while administrative duties, care of instruments, library, &c., are to be under the control of an inspector. The astronomical service is placed under M. C. Lagrange, and meteorology under M. A. Lancaster, each of whom will submit a report quarterly to the Minister of the Interior upon the work of his particular department.

THE record of an active and useful life is contained in a memoir of Dr. T. Sterry Hunt, F.R.S., by Mr. James Douglas, read before the American Philosophical Society in April last, and just published in separate form by Messrs. MacCalla and Co., Philadelphia. As a chemist Dr. Hunt was prominent nearly half a century ago, not only in the field of original investigation, but as one of the first interpreters of the new chemistry then being taught by Gerhardt. As a geologist his work was almost confined to the crystalline and palaeozoic rocks, and he brought his chemical knowledge to bear upon the geological problems concerning their genesis. Mr. Douglas's memoir contains a number of interesting notes. The following extract from a letter written by Hunt from Paris in 1855 is of interest in connection with the production and cost of aluminum at the present time:—"I bring you some aluminum with a little note from Sie. Claire Deville, the discoverer. As for aluminum, it is still very rare; perhaps 100 lbs. have been made by Deville for the Emperor, who has defrayed from his own purse the experiments. Rousseau, the greatest fabricant of rare chemicals in France, sells it, however, at three and a-half cents a gram—the price of gold—and everybody buys specimens of it at that price, so that he can hardly supply the demand." In Mr. Douglas, Dr. Hunt's work has found an appreciative recorder.

THE British Mycological Society held a most successful meeting, under the auspices of the Dublin Naturalists' Field Club, at Dublin, from September 19-24. Prof. Johnson arranged a most interesting series of excursions to Houth, Powerscourt, Brackenstown, Ballyarthur, The Woodlands, Lucan, and Dunran, and his labours were rewarded by more than 100 species being added to the published list of Mr. Greenwood Pim of "the fungi of the counties of Dublin and Wicklow." Some rare fungi were collected, including *Ammonia strobiliformis*, *Namoria crinita*, *Polyporus Wynneae*, and *Hypocrea splendens*. Interesting papers were read by the President, Dr. C. B. Plowright, on "Notes and comments on the Agaricaceae of Great Britain," "A clover destroying fungus," "Eriksson's cereal rusts," Mr. H. Wager, on "A parasitic fungus on *Euglena*," Mr. Greenwood Pim, "Notes on new and rare moulds," Dr. McWeeney, "Observations on two sclerotia occurring on the stems of potato," and Mr. Soppitt, "Notes on rare Uredineae."

THE *Agricultural Gazette of New South Wales* for July contains an interesting account, by Mr. J. H. Maiden, Government Botanist at Sydney, of a botanical exploration of Mount Kosciuszko, the highest mountain in Australia, 7328 feet above the level of the sea. Even at midsummer (January 1897) the temperature was only 1.5° above the freezing point at noon, and the climate of the mountain is not adapted for a sanatorium, as has been suggested, owing to the searching south-westerly winds. A list of the species gathered is given, the most largely represented orders being the Ranunculaceae, Leguminosae, Myrtaceae, Compositae, and Gramineae. There

is no mention in the list of any species of Saxifragaceae or Primulaceae, and only one each is recorded of Crassulaceae and Gentianaceae.

In a "Note on Stokes's Theorem," Mr. A. G. Webster contributes to the *Proceedings of the American Academy of Arts and Sciences*, xxxii. 20, a very simple proof of the expressions for the components of the curl of a vector point-function in terms of orthogonal curvilinear coordinates, which he obtains without the laborious process of transformation from rectangular axes.

THE *Revue générale des Sciences* has brought to light a new student of geometry in the form of Father Cyprien, of the Monastery of Mount Athos. This monk, who turns out to have been formerly a well-known explorer, Prince C. Wiasemsky, contributes to the pages of the *Revue* an interesting note on what he calls the "transcribed spheres" of regular polyhedra, viz. spheres touching the edges of polyhedra, and various relations between the radii of spheres transcribed to the regular tetrahedron, cube, octahedron, dodecahedron, and icosahedron are established.

PROF. ORESTE MURANI contributes to the *Rendiconti del R. Istituto Lombardo*, xxvi. 4, some interesting observations on stationary Hertzian waves as studied with the use of a coherer. The experiments were undertaken with a view of elucidating the phenomenon of multiple resonance indicated by the experiments of Sarasin and De la Rive, who by using resonators of different sizes had obtained indications of waves of different lengths. Instead of a resonator, Prof. Murani used a coherer, whose distance from the metallic reflector could be varied. On the hypothesis that the waves given off by the oscillator were simple waves, it would be natural to expect that the galvanometric deviations due to the coherer should vanish at the nodes and become a maximum at the loops. The actual observations, however, give no indications of such maxima and minima, thus favouring the view that the radiations emitted by the primary are not simple, but are composed of an infinity of waves of different periods.

THE invention of the cinematograph has led to a large demand for films, and these of considerably greater length than was previously required. We read in the *British Journal of Photography* (September 23) that the Eastman Kodak Company of Rochester, New York, have contracted to manufacture three photographic films of a length of 50,000 feet each, i.e. 9 miles 826 yards 2 feet long. These films have been ordered by Mr. Dunn for use in a machine of the kinoscope type, the "Celiograph," of which he is the inventor. It is interesting to note the cost of such strips. The Eastman Company, according to the same account, charges 10,000 dollars for each roll, making in all 30,000 dollars for 150,000 feet, or about 1000 dollars a mile. It is possible now literally to take photographs by the mile.

A CATALOGUE of the scientific works in the Royal Zoological Anthropological-Ethnographical Museum in Dresden has been prepared under the direction of Dr. A. B. Meyer, and is published by Messrs. K. Friedlander and Son, Berlin. The works are arranged alphabetically according to authors, and systematically in subjects.

HEIMINTHOLOGISTS will welcome the contributions to the anatomy and histology of Nemertean worms, which Dr. Bohmig publishes in the current number of the *Zeitschrift für Wissenschaftliche Zoologie*. Two species are described in detail, the one (*Stichonemertea grecoensis*) discovered by Dr. Bohmig himself six years ago in a freshwater pond in the botanic gardens of Graz; and the other (*Gononemertea chalcophora*),

found by Prof. von Graff in one of the hot-houses of the same gardens in 1879. The same number of the *Zeitschrift* contains also a paper, by W. Karawasew, on the changes which the internal organs of ants undergo during their metamorphosis. The observations recorded were made on female larvae of *Lasius flavus*, and are chiefly of a histological nature.

A PAPER on induction coils, read by Mr. A. Apps before the Roentgen Society, and one by Dr. I. MacIntyre on contact breakers, appear in the *Archives of the Roentgen Ray* (vol. iii No. 1), together with a report of the discussions which took place upon them at the meeting at which they were read. Unstinted praise is awarded to the excellent mechanical construction and performance of British made instruments. Thus, "The possessor of a good induction coil made by our leading instrument makers should cherish it as the violin-player cherishes his Stradivarius or his Guarnerius." Mr. T. C. Porter gives an extended account of his researches on Roentgen rays, already briefly described by him in these columns. Mr. Campbell Swinton summarises some of his recent work, and Drs. Norris Wolfenden and F. W. Forbes-Ross describe the action of Roentgen rays upon the growth and activity of bacteria and micro-organisms.

THE second edition of a "Catalogue of Scientific and Technical Periodicals," by Prof. H. Carrington Bolton, has just been published by the Smithsonian Institution. The catalogue contains particulars concerning the principal independent periodicals of every branch of pure and applied science published in all countries from 1665 to the present time. Medicine has been excluded from the list, but anatomy, physiology, and other branches of medical science have been admitted. The periodicals are arranged in alphabetical order, and they number nearly nine thousand. The date of publication of each volume of the journals entered in the catalogue is shown by means of chronological tables, by the use of which it is possible to find the date of a given volume in a given series, or the number of a volume when the date is known. The periodicals are indexed according to subjects, as well as arranged alphabetically according to their titles. The preparation of the volume (which runs into 1247 pages) must have involved an immense amount of work, and men of science will be grateful to the Smithsonian Institution for the new edition of this useful bibliography of the scientific press.

THE following are among the forthcoming publications announced by Mr. Wilhelm Engelmann (Leipzig):—"Repertorium der Zoologie," by Karl Eckstein, second revised edition, "Catalogus Hymenopterorum hucusque descriptorum systematicus et synonymicus," by C. G. de Dalla Torre, Volumen iv. Braconidae; "Monographien afrikanischer Pflanzenfamilien und Gattungen," edited by A. Engler, i. Moraceae (excl. Ficus), prepared by A. Engler; ii. Melastomataceae, prepared by E. Gilg; "Elemente der Mineralogie begründet," by Carl Friedrich Naumann. Thirteenth completely revised edition by Ferdinand Zirkel, second part, completion of the work; "Kritik der wissenschaftlichen Erkenntnis Eine vorurteilsfreie Weltanschauung," by Dr. Heinrich von Schöeller, "Grundriss der Psychologie," by Prof. Wilhelm Wundt, third revised edition; "Untersuchungen über Strukturen," by Prof. O. Butschli; "Grundriss einer Geschichte der Naturwissenschaften," by Friedrich Dannemann, vol. ii, "Monographie der Turbellarien," by Ludwig von Graff, vol. ii; "Handbuch der Blütenbiologie," founded upon Hermann Müller's work, by Paul Knuth; vol. ii. second part, Lobeliaceae bis Coniferae; "Die Vegetation der Erde Sammlung pflanzen-geographischer Monographien," edited by A. Engler and O. Drude, vol. iii. Caucasus, by G. E. Radde.

MR. EDWARD ARNOLD announces:—"Lectures on Theoretic and Physical Chemistry," by G. R. Van 't Hoff, translated by Prof. R. A. Lehfeldt; "An Experimental Course of Chemistry for Agricultural Students," by T. S. Dymond; "Elementary Physical Chemistry," by Ch. Van Deventer, with an introduction by G. R. Van 't Hoff, translated by Prof. R. A. Lehfeldt; "An Illustrated School Geography," by Dr. Andrew J. Herbertson, and a new edition of "Animal Life and Intelligence," by Prof. C. Lloyd Morgan.—Messrs G. Bell and Sons' list includes "Domestic Hygiene," by Dr. W. A. Williams.—Messrs. J. and A. Churchill's announcements include "A Synopsis of Surgery," by R. F. Tobin; and a new edition of Squire's "Companion to the British Pharmacopœia"—Messrs. Harper and Brothers' list contains, "A Thousand Days in the Arctic," by F. G. Jackson, 2 vols., illustrated.—Mr. W. H. Helmenann promises "A View of the World in 1900," a new geographical series, edited by H. J. Mackinder, in 12 vols. (1) "Britain and the North Atlantic," by the editor, (2) "Scandinavia and the Arctic Ocean," by Sir Clements R. Markham, F.R.S.; (3) "The Mediterranean and France," by Elsie Reclus; (4) "Central Europe," by Dr. Joseph Patsch; (5) "Africa," by Dr. J. Scott Kelie, (6) "The Near East," by D. G. Hogarth, (7) "The Russian Empire," by Prince Kropotkin; (8) "The Far East," by Archibald Little, (9) "India," by Colonel Sir Thomas Holdich, (10) "Australia and Antarctica," by Dr. H. O. Forbes, (11) "North America," and (12) "South America," by American authorities.—Messrs. Smith, Elder, and Co. will publish. A new edition, with additional plates, of "Electric Movement in Air and Water," by Lord Armstrong, F.R.S.

THE additions to the Zoological Society's Gardens during the past week include a Green Monkey (*Ceropithecus callosus*) from West Africa, presented by Mr. Cecil Alden; a Ring-tailed Coati (*Nasua risa*) from South America, presented by Mr. W. C. Way, six Spotted Tinamous (*Notura maculosa*) from Buenos Ayres, presented by Mr. Ernest Gibson; two Chameleons (*Chamaeleo vulgaris*) from North Africa, presented by Mr. W. H. Rosenberg; three young Lions (*Felis leo*, ♂ & ♀) from Africa, a Sumatran Rhinoceros (*Rhinoceros sumatrensis*, ♀) from Malacca, two Ems (*Drometrus naves hollandiae*), ten Cunningham's Skinks (*Egernia cunninghami*), a Black and Yellow Cyclocus (*Tiliqua nigro-lutea*) from Australia, a Jardine's Parrot (*Psephenops gahani*) from West Africa, a Red-sided Eucalyptus (*Eucalyptus pectoralis*) from New Guinea, two Reticulated Pythons (*Python reticulatus*) from the East Indies, deposited; a Common Sandpiper (*Tringoides hypoleucos*), two Little Ringed Plovers (*Actitis curvicauda*), European, purchased.

OUR ASTRONOMICAL COLUMN.

THE LARGE SUN SPOT.—The spot on the solar disc which appeared on September 3 last at the eastern limb, and which, when on the central meridian (September 9), was the probable origin of the aurora and magnetic storm, has again (September 30) made its appearance on the eastern limb, having been of sufficient dimensions to last a period of rotation of the sun. The spot is accompanied by several others of smaller size, and its umbra is divided into three separate parts, which form objects of interesting observation. Even in one day considerable changes have been noted to have taken place in the smaller spots in its neighbourhood, although the large one has not shown any marked change. It will be interesting to know whether another aurora and concurrent magnetic storm will be observed and recorded when the spot reaches the central meridian (which will take place on October 6), as was the case at its last meridian passage.

NEW TEACHING OBSERVATORY FOR THE CALIFORNIAN UNIVERSITY.—We have received a circular from the director (Mr. A. O. Leuschner) of the students' observatory of the Uni-

versity of California, from which we make the following brief summary.—The trustees of the "Phebe Hearst Architectural Plan for the University of California" have inaugurated an international competition to secure the most suitable plan for the erection of new buildings in place of the present ones on the University grounds at Berkeley. The buildings are to satisfy every need of a modern University of the highest rank. Among these buildings will be an astronomical observatory especially adapted to the training of young men and women for the profession of astronomy in all its branches, and its equipment will be such as best to serve the purposes of the highest instruction in all branches of astronomy. It is stated that the new observatory is not meant to conflict with the Lick Astronomical Department of the University, for these students are only admitted who are supposed to have shown a marked ability for observation and independent research, and who receive from the astronomers a higher inspiration, and are guided by them in their first investigations in such special lines as can be best carried on at the Lick Observatory. While the main feature of the Berkeley department will be to give proper instruction to its students, the equipment of the observatory is proposed to be sufficiently complete to give ample opportunity for the higher work of research that the instructors and advanced students may be in a position to undertake. The object of the circular is, as the writer mentions, "to state in detail my ideas concerning the proposed new observatory, and to seek the advice of men prominent in the science of astronomy and in astronomical instruction elsewhere." That the observatory will be fully equipped and suitable for the work intended to be accomplished there will be little doubt, and the question of cost is evidently a minor detail, for the Trustees of the Plan invite opinion and request "suggestions irrespective of cost which . . . will better adapt the new observatory for the purposes which it is to serve."

Some of the instruments suggested are an equatorial refractor of an aperture not greater than 16 inches; four smaller telescopes ranging from 6 to 10 inches aperture, one being a reflector; complete accessories for visual photographic, spectroscopic and photometric work, a 4 inch meridian circle, and four transit and zenith telescopes. The circular gives also details of the sizes of all the rooms for the instruments, laboratories, lectures, library, &c., which it is proposed to build.

ANNUAL REPORT OF THE CAMBRIDGE OBSERVATORY.—In his report to the Observatory Syndicate, which covers a period twelve months ending May last, Sir Robert Ball states that the meridian instrument of the observatory has been devoted especially to the perfection of a complete catalogue (which is ready for the press), by re-observing stars of which a single observation had only been obtained. It has also been employed in the determination of accurate places of a list of occultation stars at the request of Colonel Tupman. The Northumberland equatorial has been occasionally used for examining fixed stars and planets, but is chiefly employed when visitors are admitted.

The work of the Newall telescope has been continued by Mr. H. F. Newall on the same lines as in former years, namely, the determination of the velocities of stars in the line of sight as measured photographically. The stars chiefly used were those of the solar type. In all 111 photographs of sixty minutes' exposure each were obtained, giving material for the determination of velocity of forty four stars. Twenty of these stars were of magnitudes greater than 2.5, and are included in the Potsdam observations made in 1888-91; the remainder lie between magnitudes 2.5 and 4.0, and were fainter than could be successfully dealt with at Potsdam. Of these plates eighty-three have been measured once, and twenty twice.

The report further states that the new photographic telescope is now finished at Sir Howard Grubb's works, and that the building to house it has been practically completed.

ANNUAL PUBLICATION OF THE OBSERVATORY OF RIO DE JANEIRO FOR 1898.—This yearly publication of the Astronomical Observatory of Rio de Janeiro is the fourteenth of the present series, and will be found to contain a great deal of useful information in addition to the ordinary data usually found in astronomical almanacs. There will be found tables for the reduction of meteorological observations, and for calculating altitudes from barometric observations by the methods of Laplace, Bessel, Cruik, Weissenmann. meteorological observations for several towns, such as Rio de Janeiro, Santa Cruz, Uberaba, contained in Part vi, which also includes the magnetic ele-

ments observed at Brazil by the Holland Commission. The last section is devoted to some miscellaneous data, and contains, among other matters, tables for determining, rapidly and approximately, the elements of a triangulation by the method proposed by Mr. Francis Galton.

RECENT ADVANCES IN SCIENCE, AND THEIR BEARING ON MEDICINE AND SURGERY¹

THE honour of being invited to deliver the second Huxley Lecture has deeply moved me. How beautiful are these days of remembrance which have become a national custom of the English people! How touching is this act of gratitude when the celebration is held at the very place wherein the genius of the man whom it commemorates was first guided towards its scientific development! We are filled not alone with admiration for the hero, but at the same time with grateful recognition of the institution which planted the seed of high achievement in the soul of the youthful student. That you, gentlemen, should have entrusted to a stranger the task of giving these feelings expression seemed to me an act of such kindly sentiment, implying such perfect confidence, that I at first hesitated to accept it. How am I to find in a strange tongue words which shall perfectly express my feelings? How shall I, in the presence of a circle of men who are personally unknown to me, but of whom many knew him who has passed away and had seen him at work, always find the right expression for that which I wish to say as well as a member of that circle itself could? I dare not believe that I shall throughout succeed in this. But if, in spite of all, I repress my scruples it is because I know how indulgently my English colleagues will judge my often incomplete statements, and how fully they are inclined to pardon deficiency in diction if they are convinced of the good intentions of the lecturer.

PROFESSOR HUXLEY'S WORK

I may assume that such a task would not have been allotted to me had not those who imposed it known how deeply the feeling of admiration for Huxley is rooted within me, had they not seen how fully I recognised the achievements of the dead master from his first epoch-making publications, and how greatly I prized the personal friendship which he extended towards me. In truth, the lessons that I received from him in his laboratory—a very modest one according to present conditions—and the introduction to his work which I owe to him, form one of the pleasantest and most lasting recollections of my visit to Kensington. The most competent witness of Huxley's earliest period of development, Prof. Foster, presented in the first of these lectures a picture of the rapidly increasing extension of the biological knowledge, which must have excited not only our admiration, but also the emulation of all who study medicine. Upon me the duty is incumbent of incorporating with this presentation the newer strides of knowledge and of stating their influence upon the art of healing. So great a task is this that it would be presumptuous even to dare to attempt its accomplishment in a single lecture. I have decided, therefore, that I must confine myself to merely sketching the influence of biological discoveries upon medicine. In this way also will the example of Huxley be most intelligible to us. I must here make a confession. When I tried to ascertain how much time would be required to deliver my lecture as I had prepared it, I found, to my regret, that its delivery would occupy nearly double the time assigned to me. I had therefore to reduce it to about half of its original dimensions. This could only be done by means of very heroic cuts, seriously damaging in more than one place my chain of ideas. If, therefore, you should find, gentlemen, that my transitions from one point to the other occasionally are of a somewhat sudden and violent character, I trust you will bear with me and remember that, if you should take the trouble of reading my address afterwards, you will be less shocked than you may be to-day by my statements when they appear in print.

THE BEGINNINGS OF BIOLOGY.

Huxley himself, though trained in the practical school of Charing cross Hospital, won his special title to fame in the domain of biology. As a matter of fact, at that time even the

name of biology had not come into general use. It was only recently that the idea of life itself obtained its full significance. Even in the late middle ages it had not sufficient strength to struggle through the veil of dogmatism into the light. I am glad to be able to-day for the second time to credit the English nation with the service of having made the first attempts to define the nature and character of life. It was Francis Glisson, who, following expressly in the footsteps of Paracelsus, investigated the *princippium vite*. If he could not elucidate the nature of life, he at least recognised its main characteristic. This is what he was the first to describe as "irritability," the property on which the energy of living matter depends. How great was the step from Paracelsus to Glisson, and how we may continue—from Glisson to Hunter! According to Paracelsus, life was the work of a special *spiritus*, which set material substance in action, like a machine; for Glisson, matter itself was the *princippium energeticum*. Unfortunately, he did not confine this dictum to living substances only, but applied it to substance in general, to all matter. It was Hunter who first announced the specific nature of living matter as contrasted with non-living, and he was led to place a *materia vita diffusa* at the head of his physiological and pathological views. According to the teaching of Huxley and Hunter, the blood supplies the plant materials of physiology as well as the plastic exudates of pathology. Such was the basis of the new biological method, if one can apply such an expression to a still incomplete doctrine, in 1842, when Huxley was beginning his medical studies at Charing cross Hospital. It would lead too far afield were I to recount in this place how it happened that I myself, like Huxley, was early weaned from the pernicious doctrines of humoral pathology.

THE DEVELOPMENT OF BIOLOGY

When Huxley himself left Charing-cross Hospital, in 1846, he had enjoyed a rich measure of instruction in anatomy and physiology. Thus trained, he took the post of naval surgeon, and by the time that he returned, four years later, he had become a perfect zoologist and a keen-sighted ethnologist. How this was possible, any one will readily understand who knows from his own experience how great the value of personal observation is for the development of independent and unprejudiced thought. For a young man who, besides collecting a rich treasure of positive knowledge, has practised the plastic arts to the extent of a critical judgment, a long sea voyage and a peaceful sojourn among entirely new surroundings afford an invaluable opportunity for original work and deep reflection. Freed from the formalism of the schools, thrown upon the use of his own intellect, compelled to test each single object as regards properties and history, he soon forgets the dogmas of the prevailing system and becomes first a sceptic, and then an investigator. This change, which did not fail to affect Huxley, and through which arose that Huxley whom we commemorate to-day, is no unknown occurrence to one who is acquainted with the history, not only of knowledge, but also of scholars. We need only point to John Hunter and Darwin as closely-allied examples. The path on which these men have achieved their triumphs is that which biology in general has trodden with ever widening strides since the end of last century—it is the path of genetic investigation. We Germans point with pride to our countryman who opened up this road with full conviction of its importance, and who directed towards it the eyes of the world—our poet-prince Goethe. What he accomplished in particular from plants others of our fellow-countrymen achieved from animals—Wolf, Meckel, and our whole embryological school. As Harvey, Haller, and Hunter had once done, so these men began also with the study of the "ovulum," but this very soon showed that the egg was itself organised, and that from it arose the whole series of organic developments. When Huxley, after his return, came to publish his fundamental observations he found the history of the progressive transformations of the contents of the egg already verified, for it was by now known that the egg was a cell, and that from it fresh cells, and from them organs, arose. The second of his three famous papers—that on the relationship between man and the animals next beneath him—linned in exemplary fashion the parallelism in the earliest development of all animal beings. But beyond this it stepped boldly across the border-line which tradition and dogma had drawn between man and beast. Huxley had no hesitation in filling the gaps which Darwin had left in his argument, and in explaining that "in respect of

¹ The second Huxley lecture, delivered by Prof. R. Virchow at the opening of the winter session of Charing Cross Hospital Medical School, on October 3. Reprinted from the *Lancet*.

substance and structure man and the lower animals are one." Whatever opinion one may hold as to the origin of mankind, the conviction as to the fundamental correspondence of human organisation with that of animals is at present universally accepted.

OMNIS CELLULA E CELLULA

The greatest difficulty in the advance of biology has been the natural tendency of its disciples to set the search after the unity of life in the forefront of their inquiries. Hence arose the doctrine of vital force, an assumption now discarded, but still revealing its influence from time to time in isolated errors. No satisfactory progress can be made till the idea of highly-organised living things as units had been set aside, till it was recognised that they were in reality organisms, each constituent part of which had its special life. Ultimate analysis of higher animals and plants brings us alike to the cell, and it is these single parts, the cells, which are to be regarded as the factors of existence. The discovery of the development of complete beings from the ova of animals and the germ cells of plants has bridged the gap between isolated living cells and complete organisms, and has enabled the study of the former to be employed in elucidating the life of the latter. In a medical school where the teaching is almost exclusively concerned with the human beings this sentence should be writ large—"The organism is not an individual, but a social mechanism." Two corollaries must also be stated—(1) that every living organism, like every organ and tissue, contains cells; (2) that the cells are composed of organic chemical substances, which are not themselves alive. The progress of truth in these matters was much retarded by that portion of Schwann's cell theory which sought to establish the existence of free cell-formation, which really implied the revival of the old doctrine of spontaneous generation. This belief was gradually driven out of the domain of zoology, but in connection with the formation of plastic exudates found a sanctuary in that of pathology. I myself was taught the discontinuity of pathological growths—a view which would logically lead back to the origin of living from non living matter. But enlightenment in this matter came to me. At the end of my academical career I was acting as clinical assistant in the eye department of the Berlin Hospital, and I was struck by the fact that keratitis and corneal wounds healed without the appearance of plastic exudation, and I was thus led to study the process of inflammation in other non-vascular structures, such as articular cartilages and the intima of the larger vessels. In no one of these cases was plastic exudation found, but in all of them were changes in the tissue cells. Turning next to vascular organs, and in particular those which are the common seats of exudation processes, I succeeded in demonstrating that the presence of cells in inflammatory exudates was not the result of exudation, but of multiplication of pre-existing cells. Extending this to the growth in thickness of the long bones—which was ascribed by DuRoi to organisation of a nutritious juice exuded by the periosteal vessels—I was thus eventually able to extend the biological doctrine of *omnis cellula e cellula* to pathological processes as well; every new formation presupposing a matrix or tissue from which its cells arise and the stamp of which they bear.

HEREDITY.

Herein also lies the key to the mystery of heredity. The humoral theory attributed this to the blood, and based the most fantastic ideas upon this hypothesis; we know now that the cells are the factors of the inherited properties, the sources of the germs of new tissues and the motive power of vital action. It must not, however, be supposed that all the problems of heredity have thus been solved. Thus, for instance, a general explanation of theromorphism, or the appearance of variations recalling the lower animals, is still to be found. Each case must be studied on its merits, and an endeavour made to discover whether it arose by atavism or by hereditary transmission of an acquired condition. As to the occurrence of the latter mode of origin, I can express myself positively. Equally difficult is the question of hereditary diseases; the new generally assumed to depend on the transmission of a predisposition which is present, though not recognisable, in the earliest cells, being derived from the paternal or maternal tissues. But the most elaborately constructed doctrines as to the hereditaryness of a given disorder may break down before the discovery of an actual *causa viva*. A notable example of this is found in the case of leprosy, the

transmission of which by inheritance was at one time so firmly believed in that thirty years ago a law was nearly passed in Norway forbidding the marriage of members of leprosy families. I myself, however, found that a certain number of cases at any rate did not arise in this way, and my results were confirmed by the discovery of the leprosy bacillus by Armauer Hansen. In a moment the hereditary theory of the disease was overthrown and the old view of its acquirement by contagion restored. Precisely the same happened a few decades earlier with regard to favus and scabies. Another instructive condition is that known as Heterotopia in which fragments of tissues or organs are found dwelling in a situation other than that which is normal to them. This is particularly the case with certain glands, such as the thyroid and suprarenal, but is also known with cartilage, teeth, and the various constituents of dermoids. It no doubt occurs by process of transplantation, the misplaced tissues developing no new properties, but merely preserving their normal powers of growth. The attempt to generalise from this fact and to attribute all tumour formation to this cause carries the idea beyond its proper scientific limits.

PARASITISM AND INFECTION

With regard to the subject of parasitism, the progress of scientific observation was retarded for centuries by the prevalence of the assumption made by Paracelsus that disease in general was to be regarded as a parasite. Pushed to its logical conclusion, this view would imply that each independent living part of the organism would act as a parasite relatively to the others. The true conception of a parasite implies its harmfulness to its host. The larger animal parasites have been longest known, but it is not so many years since their life-history has been completely ascertained and the nature of their cysts explained, while an alternation of generations has been discovered in those which are apparently sexless. Very much more recent is the detection of the parasitic protozoa, by which the occurrence of the tropical fevers may be explained. As yet we have not complete knowledge as to their life-history, but we hold the end of the chain by which this knowledge can be attained. The *ditto* of the infectious diseases are, however, the work of the minutest kind of parasitic plants, bacteria, the scientific study of which may be said to date from Pasteur's immortal researches upon putrefaction and fermentation. The observation of microbes under exact experimental conditions, and the chemical investigation of their products opened up the modern field of bacteriology, a science among the early triumphs of which were the discoveries of the bacilli of tubercle and Asiatic cholera by Robert Koch. In connection with this subject, three important landmarks require comment. One is the necessity for distinguishing between the cause and the essential nature of infectious diseases, the latter of which is determined by the reaction of the tissues and organs to microbes. Secondly, there is the relation between the smaller parasites and the diseases determined by them. This may be summed up in the general word (introduced by Prof. Virchow himself—"infection." But to assume that all infections result from the action of bacteria is to go beyond the domain of present knowledge, and probably to retard further progress. The third point is the question as to the mode of action of infection. It is only the larger parasites whose main effect is the devouring of parts of their hosts; the smaller act mainly by the secretion of virulent poisons. The recognition of this latter fact has led to the brilliant work of Lister on the one hand, and to the introduction of serum therapeutics on the other.

ANISEPTIC SURGERY

It would be carrying costs to Newcastle were I to sketch in London the beneficial effects which the application of methods of cleanliness has exercised upon surgical practice. In the city wherein the man still lives and works who, by devising this treatment, has introduced the greatest and most beneficent reform that the practical branches of medical science have ever known, every one is aware that Lord Lister, on the strength of his original reasoning, arrived at practical results which the new theory of fermentative and septic processes fully confirmed. Before any one had succeeded in demonstrating by exact methods the microbes which are active in different diseases, Lister had learnt, in a truly prophetic revelation, the means by which protection against the action of putrefactive organisms can be attained. The opening up of further regions of clinical medicine to the knife of the surgeon and a perfect revolution in

the basis of therapeutics have been the consequence. Lord Later, whom I am proud to be able to greet as an old friend, is already and always will be reckoned amongst the greatest benefactors of the human race. May he long be spared to remain at the head of the movement which he called into existence.

ARTIFICIAL IMMUNISATION

It remains for me to say a word concerning the other great problem, the solution of which the whole world is awaiting with anxious impatience. I refer to the problem of immunity and its practical corollary, artificial immunisation. It has already happened once that an Englishman has succeeded in applying this to the definite destruction of at least one of the most deadly infectious diseases. Jenner's noble discovery has stood its trial as successfully, except in popular fancy, as he hoped. Vaccine is in all hands; vaccination is, with the aid of Governments, spreading continually. Pasteur also laboured with determination; others have followed him, and the new doctrine of antitoxins is continually acquiring more adherents. But it has not yet emerged from the conflict of opinions, and still less is the secret of immunity itself revealed. We must become well accustomed to the thought that only the next century can bring light and certainty on this point. Prof. Virchow, having referred with pride to the influence of cellular pathology in modern treatment, entailing, as it does, the principle of destroying the focus of disease by early operation, concluded his lecture in these words:—May the Medical School of Charing-cross Hospital continue upon the newly-opened path with zeal and good fortune. But may its students at the same time never forget that neither the physician nor the naturalist dares to dispense with a cool head and a calm spirit, with practical observation and critical judgment.

CHEMISTRY AT THE BRITISH ASSOCIATION

ALTHOUGH no epoch-making discoveries can be recorded amongst the contributions to the Chemical Section this year, the work of the Section was full of interest and attraction. A very wide range of subjects was included in the programme, and the presence of many past presidents of the Section added very considerably to the interest of the meeting. The announcement of the discovery of two new elements, *Monium* and *Xenon*, must constitute a record for the first two days of the meeting, although new elements, especially amongst the rarer earths and gases, hardly excite the interest that similar discoveries did some years back. *Monium* is described in Sir William Crookes' address. It is an added element culled "from the waste heaps of the mineral elements," characterised by a group of distinctive lines in the ultra violet end of the spectrum, and having an atomic weight of about 118, between those accepted for yttrium and lanthanum respectively. "*Xenon*" was described by Prof. Ramsay and Dr. Travers in their paper on "The extraction from air of the companions of Argon and on Neon." It accompanies krypton and metargon in the last fractions of liquefied argon, and is easily separated from the latter on account of its higher boiling point. It remains behind after the other two gases have evaporated, and is the heaviest of the three gases. *Xenon*, "the stranger," shows an analogous spectrum to argon, but differing entirely in the position of the lines. With the ordinary discharge the gas shows three lines in the red, and about fifty very brilliant lines in the blue, while with the jar and spark gap these lines disappear, and are replaced by four brilliant lines in the green, intermediate in position between the two groups of argon lines. The remainder of the paper dealt with the successful issue of the search for "an undiscovered gas"—the subject of Prof. Ramsay's presidential address to the Section at Toronto. This gas should have an atomic weight higher than that of helium by about 16 units, and lower than that of argon by about 20. The determination of the atomic weight of neon gave the figure 19.2; it would therefore follow fluorine, and precede sodium in the periodic table. Like argon and helium it is monatomic; it is present in the air in the proportion of about 1 part in 40,000. Prof. Emerson Reynolds added a note on the position of helium, argon, krypton and neon in his diagrammatic representation of the relations of the elements, and pointed out that their atomic weights as yet determined were well in accord with his representation of the periodic law. Amongst other papers on inorganic chemistry, Prof. F. Clowes gave an account of his work on the action of magnesium on cupric sulphate solutions, under the title of "Equivalent replacement of metals." The reaction was studied with both hot and cold solutions, and under various conditions of concentration. In all cases cuprous oxide is formed, and hydrogen is evolved side by side with the deposition of the copper. This evolution of hydrogen is attributed in part, but not wholly, to the presence of free sulphuric acid formed by hydrolysis of the cupric sulphate and accompanied by the separation of a basic salt. Prof. Hodgkinson and Mr. Coote, in a paper on "Alkaline chlorides and sulphates of the heavy metals," pointed out that many solid sulphates, whether containing water of crystallisation or anhydrous, give off chlorine in addition to oxygen when gently heated with potassium or sodium chlorate. A residue of the alkaline sulphate and chloride and the oxide and chloride of the metal is left behind. The evolution of chlorine and oxygen occurs at temperatures very little above 100° C. Mr. R. G. Durrant described a series of "Green cobaltic compounds" he had obtained by oxidising potassium cobaltous oxalate with hydrogen peroxide; similar results follow the oxidation of cobaltous salts in presence of glycolates, citrates, malates, lactates or succinates of the alkali metals.

In another branch of the science, physical chemistry, Prof. Sydney Young contributed a most lucid and interesting account of his researches on the "Thermal properties of gases and liquids." The subject is one which has engaged Prof. Young's attention for the past eleven years, and his descriptive summary of his labours was therefore received with special interest. One chief aim of these investigations has been to ascertain whether the generalisations of Van der Waals regarding the relations of pressure, temperature and volume for both gases and liquids, are really true, and if not, whether the observed deviations would throw any light on the modifications which must be made in Van der Waals' fundamental formula in order to bring it into accurate agreement with the experimentally determined isothermals for liquids and gases. The vapour pressures and specific volumes of a number of substances were therefore determined, both as liquid and as saturated vapour, from low temperatures to their critical points. Twenty-six substances have been examined altogether, including paraffins, benzene and its haloid derivatives, esters, alcohols and acetic acid, and the data obtained allow of a synoptic classification in respect to the physical constants. Amongst other points of interest the results show that the molecules of the alcohols at moderate temperatures are polymerised in the liquid, but not in the gaseous state, whilst there is polymerisation in both states in the case of acetic acid, also, that the molecules of the alcohols and acetic acid appear to be polymersized to a considerable extent at the critical point. Prof. Young also described his methods for the determination of the critical constants and of the specific volumes of both liquid and saturated vapour. Ample proof was obtained in the course of these investigations that the views of Andrews regarding the behaviour of a substance in the neighbourhood of the critical point are correct, and also that the vapour pressure of a pure substance is quite independent of the relative volumes of liquid and vapour. The method of fractional distillation of liquids adopted for the preparation of pure substances was described, and the apparatus was exhibited at work; it has thus been found quite feasible to separate perfectly pure normal and iso pentane from American petroleum. The Earl of Berkeley described the methods he has adopted for the more exact determination of the densities of crystals, in which special precautions are taken to eliminate errors in the measurement of temperature, volume and mass, occlusion of mother liquor, and absorption of moisture. The determinations recorded were made in carbon tetrachloride, a maximum divergence of 0.04 per cent. being shown as the result of four determinations of the density of potassium carbonate crystals. Under the head of physical chemistry the joint-meeting with Section A on the "Results of the recent Eclipse expeditions" has been referred to in connection with the doings of the Physics Section. The modern photographic plate as a sensitive medium for the recording of chemical action was the subject of several interesting communications, notably that of Dr. W. J. Russell on "The action exerted by certain metals and other organic substances on a photographic plate." Some account of these researches has already been given in NATURE. Dr. Russell showed a series of slides illustrating the action of printer's ink, wood, dry

copal varnish, turpentine, drying oils, essential oils and metals on a photographic plate, in the dark, and detailed his method of experiment. Actual contact is not necessary to obtain the action; it takes place also at a distance. The time required is dependent upon the temperature, in the earlier experiments it required a week to produce a developable image, but by raising the temperature to 55°C. considerable action was recorded in five minutes. Sheets of gelatine, celluloid, gutta-percha and collodion do not hinder the action, when placed as screens between the active surface and the plate. Hydrogen peroxide is regarded by Dr. Russell as most probably the active agent in all these actions, but further experiments are in progress to decide this more definitely. In a complementary paper by Mr. C. H. Boehmley, on "The action of certain substances on the undeveloped photographic image," evidence was adduced to show that printer's ink can after a time act on a photographic plate and destroy the "latent image." The vapour of hydrogen peroxide and turpentine have the same effect. Whereas, therefore, hydrogen peroxide acting for a short time or in small quantity produces a developable image, by more prolonged action or in a more concentrated form it acts as an oxidiser and destroys the image. Probably both actions take place simultaneously, and the result at any given instance depends on their relative intensities. Prof. Percy Frankland contributed an additional photographic action—that of bacteria. By placing gelatine cultures of *Bacillus coli communis* and of *Proteus vulgaris*, either in juxtaposition or at a distance of half an inch from a photographic plate, definite developable images were obtained. The action is stopped by glass or mica, and is therefore not due to radiation, but to the evolution of some volatile matter which reacts with the plate. Bacterial growths which are luminous in the dark (*Photobacterium phosphorescens*) have a still greater action. The investigation is to be extended to other organic structures—vegetable and animal, living and dead. Amongst these contributions may be included an account by Dr. J. H. Gladstone and Mr. Hibbert of their further work on "The absorption of the Röntgen rays by chemical compounds," which dealt chiefly with their attempts to perfect quantitative methods of estimating the comparative densities of their radiographs. Mr. Hibbert also described an instrument he had devised for ascertaining the relative grades of the Röntgen rays.

Applied chemistry received attention under various headings. Special local interest naturally centred in Dr. J. Gordon Parker's paper on "Recent advances in the tanning industry," in which the lack of scientific methods amongst the tanners of this country was sternly criticised. Dr. Parker referred to the employment of extracts in tanning as a marked advance which had also brought about improved methods of estimating the tanning value of the materials employed in the industry, but bating and "puering" of hides by means of dog and hen excrement was stigmatised as a standing disgrace to the leather trade. American and continental tanners appear to be far ahead of their English brethren in respect to the extraction of tanning materials in the tanyard. The cold extraction processes employed here mean loss and waste. Analyses of over 300 samples of so-called waste-pen tan from forty tanyards in Great Britain having shown an average of over 9 per cent of available tannic acid. With valonia alone this represents a loss of 11, 13s 4d a ton, about 500,000 annually. In Germany and America warm extraction, which means practically complete extraction, has proved successful. The fear of darker colour in leather from the use of warm extracts is much exaggerated; as the temperature of extracting is raised, more colouring matter is dissolved, but it is difficultly soluble, and much of it is re-deposited on cooling. Mr. Vernon Harcourt exhibited and described his new "10-candle pentane lamp," which was most favourably commented on by Prof. Vernon Boys as a standard of light. Mr. Vernon Harcourt pointed out the advantages of a 10 or 16 candle standard for testing illuminating gas, over that now employed, and also the need of a large but compact standard flame. The burner is supplied with a mixture of air and gaseous pentane from a reservoir placed on a bracket at the top of the lamp. As this mixture falls down a siphon tube connecting the reservoir and the lamp, fresh air enters the former, which is provided with cross partitions, causing the air to travel backwards and forwards over the surface of the pentane and to mix with a proportion of pentane, which varies in amount with the external temperature. The arrangement of the lamp is such, however, that the variation in the proportion of pentane does not affect

the output of light. There is a casing round the burner with a conical top which steadies the flame, the upper part of which is drawn together in a long brass chimney which cuts off the light of this part of the flame. The lamp is so constructed that a cool air current issues through the middle of the argand burner, which thus gives a steady flame 60-70 mm high, having an illuminating value of rather more than ten candles. By adjusting the tube which receives the top of the flame at a height of 47 mm, the light shed horizontally is reduced to exactly ten candles. Comparisons made between four different lamps showed concordant results, their values being also in accord with the one candle pentane standard. Prof. Emerson Reynolds's experiment, illustrating "The effect on the acetylene flame of varying proportions of carbon dioxide in the gas," was of considerable interest. The experiment had arisen from a chance observation by Mr. Goodwin that expired air when mixed with acetylene appeared to increase the luminosity of the acetylene flame, and also to decrease the tendency to deposit carbon in the burners. More careful study had shown that 5-8 per cent of carbon dioxide in the gas decreased the smokiness of the flame, and especially prevented the clogging of the burners. The increase in illuminating power was certainly not marked, but the mixture containing 5 per cent of carbon dioxide gave as much light as the acetylene itself, and therefore there is a gain to this extent per volume of acetylene burned. The action of the carbon dioxide was regarded as probably due to its exerting some oxidising effect.

Agricultural chemistry was dealt with in the report of the Committee on the Carbohydrates of Cereal Straws, and by Dr. Luxmoore, who described a scheme of analysis for Dorsetshire soils, which is to be carried out with the view of obtaining a general knowledge of the soils of the county. Dr. Armstrong also contributed a preliminary report of the Committee established last year for the promotion of agriculture. Dr. Gladstone's report on the "Teaching of science in elementary schools" was followed by an interesting discussion, and Dr. Armstrong gave a suggestive account of methods he had adopted for training children in methods of original inquiry under the title of "Juvenile research." Reports were submitted by the several committees of the Section, which will be published in a *volume* in the *Transactions* of the Association. Amongst these, those on the action of light upon dyed colours, on isomeric naphthalene derivatives, on the wave length tables of the spectra of the elements, on the bibliography of agriculture, and on the electrolytic methods of quantitative analysis were continuation of previous work. Two new Committees were formed, one to investigate the relation between the absorption spectra and constitution of organic substances, and the other on the chemical and bacterial examination of water and sewage, especially in reference to establishing a uniform method for recording results. The sewage problem was also treated by Dr. Rideal, in a paper on "Standards of purity for sewage effluents."

Organic chemistry received a fair share of attention, several papers of importance, and interest being read. Prof. Noetting, of Mulhausen, described a new series of colours he had obtained from amidated aromatic amidines, the first series of amidine colours prepared. Dr. Laurie and Mr. Strange showed the results they have obtained in studying the cooling curves of fatty acids. The curve, which is very characteristic for pure fatty acids, such as palmitic and stearic, shows a marked change if 1 per cent. of another fatty acid is present, and when a larger proportion of the second acid is introduced a second latent heat point is developed, the curve showing a discontinuity below the solidifying point of the mixture. These curves given by these mixtures indicate a reproduction of the phenomena observed by Prof. Roberts-Austen in the case of certain alloys. Messrs. Fenton and Jackson showed that the oxidation of polyhydric alcohols in presence of ferrous iron proceeds on analogous lines to that of tartaric acid, "glycerate," the mixture of glyceralddehyde and dihydroxy-acetone being formed from glycerol, whilst Dr. Morrell and Mr. Crofts recorded a corresponding result on the oxidation of glucose, the alcohol group next to the aldehyde group being oxidised. The contributions in this branch of chemistry are usually too technical to interest many of the followers of the Association, but this year all organic chemists felt a special debt of gratitude to the President of the Section, Prof. Japp, not only for the value of his address to them, but also for the manner in which he had placed the methods and limitations of modern organic chemistry before a far wider field of scientific workers.

GEOLOGY AT THE BRITISH ASSOCIATION.

SO far as Section C was concerned, the Bristol meeting of the British Association was decidedly successful. The attendance at the sectional meetings was above the average, and the interest well sustained, a larger proportion than usual of the papers and reports being of a character to give rise to discussions on broad general principles, for which these occasions are pre-eminently adapted.

In some cases these discussions were curtailed from lack of time, and there was a little discontent among the more steadfast adherents to the Indoor work of the meeting that the whole of the papers should have been crowded into four days, and the Saturday and Wednesday half-day sessions dispensed with. But in a region so rich in geological interest it was desirable that every opportunity for outdoor investigation should be given to the members of the Section, especially as the weather during the meeting was singularly favourable for field-work. The popularity of the short afternoon excursions arranged for Friday, Monday and Tuesday, under the leadership of Prof. C. Lloyd Morgan and Mr. H. Pentecost, to classical sections in the vicinity of Bristol, proved that to the visiting geologists the chance of inspecting the best exposures under competent guidance was at least of equal importance to the indoor proceedings. These afternoon excursions have, during the last three or four years, become an important feature in the arrangements of the Section, and though it has been sometimes objected that they are detrimental to the attendance indoors during the later stages of the daily session, it is doubtful whether such is really the case. The difficulty of holding together an audience of notable dimensions when the sitting of the Section is prolonged late into the afternoon was felt at these meetings long before the institution of the short excursions.

The papers and reports submitted to the Section are too numerous for adequate mention, and special reference can only be made here to such as possessed wide interest or led to much debate. As frequently happens, some of the papers containing the most solid and original work attracted the least discussion.

At the opening day of the sectional meeting after the presidential address, Prof. C. Lloyd Morgan gave a clear general account of the more interesting features of the local geology, dealing especially with the places to be visited during the excursions. The lantern slides by which this address was illustrated were unfortunately almost invisible owing to the insufficient darkening of the room.

Mr. F. Wethered followed with a paper on "The building of the Clifton rocks," in which he contended for the importance of certain micro organisms in the formation of the local limestones. These "incrusting organisms," along with other forms which he described, all hitherto usually held to be of inorganic origin, are regarded by Mr. Wethered as organic growths, to which in some cases the structure of the limestone is due; and these he considers to be serviceable aids in identifying the strata. At a later session Mr. Wethered brought forward a second paper on "The work of incrusting organisms in the formation of limestone," in which he urged the claims of *Girvanella* and allied forms in the production of the oolitic structure in Jurassic rocks. Both papers were illustrated by beautiful lantern slides of rock slices prepared by the author. These papers gave rise to lively discussions, in which by some speakers the organic origin of some of the structures was strenuously denied, in his able reply, Mr. Wethered claimed that a thorough investigation of his slides by a committee of experts would convert the partial recognition which his views had already won into a thorough going acceptance of all his conclusions.

Mr. A. Strahan brought before the meeting an account of the results of the revision of the South Wales Coal field by the Geological Survey, showing the great advances which have been made in our knowledge of the structure of this important area, and the methods adopted for representing the new information upon the maps.

In a paper on "The comparative action of sub-aerial and submarine agents in rock decomposition," Mr. T. H. Holland, of the Geological Survey of India, drew attention to the wide-reaching difference between the manner of decomposition of the crystalline and igneous rocks in Southern India and in Europe, especially in the degree of hydration of the minerals. This difference, he thought, might be due to the absence of submarine action in the central portion of Southern India during the *older* geological periods, so that the rocks have been affected

only by sub-aerial weathering, and deeper portions of the earth's crust have, by long denudation, been exposed at the surface than in Europe.

Friday's session was opened by a suggestive discourse by Prof. O. C. Marsh, on "The comparative value of different kinds of fossils in determining geological age," in which the claims of the vertebrates, wherever they existed, were pressed as being the best for the purpose. As a side-issue, Prof. Marsh drew renewed attention to the Jurassic affinities of the English Wealden fauna, so that his paper provided almost unlimited scope for discussion. Most of the speakers on the subject, while acknowledging that the main point of Prof. Marsh's contention might be theoretically correct, dwelt upon the practical difficulties to the field-geologist in the collection and determination of vertebrate remains, and urged that this must prevent these fossils being used for zonal purposes except in rare instances. Another paper which provoked an interesting discussion was that of Prof. J. F. Blake, on "Aggregate deposits and their relation to zones." The author proposes the term "aggregate deposits" for strata in which fossils characterising more than one zone occur together in the same rock band. He considers that in such deposits the fossils do not lie in their natural position, but have been swept together tumultuously by strong currents. In the debate on this paper, while general approval of the term "aggregate" was expressed, there was much difference of opinion as to the manner in which such deposits had accumulated, and it was suggested that Prof. Blake had included strata of diverse origin in his proposed classification.

The two papers contributed by Mr. T. Groom, on "The age, and geological structure of the Malvern and Abberley Ranges," were good examples of careful stratigraphical investigation, and were well received. Mr. Groom's conclusions are that the Malvern axis was not an island in Cambrian and Silurian seas as generally supposed, but that it was elevated chiefly by Upper Palaeozoic crustal movements and its folds belong to the Great Hercynian system formed towards the close of the Carboniferous Period. At the same session Mr. E. Greenly announced the discovery of Arcting shales beneath the Carboniferous rocks near the Menai Bridge, and in another paper described a clear case of block uplift at Llandegfan, Menai Straits, where a train of blocks has been raised about 300 feet in the distance of one mile. Mr. Greenly also called attention to the impeding of strata in quarrying operations of the most important portion of the drift section of Moel Tryfan, and his suggestion that a committee should be appointed for the purpose of securing, while there was yet time, photographic and other records of this celebrated section was at once acted upon, and a small grant was obtained to cover the expenses.

In his paper on "The age and origin of the granite of Dartmoor, and its relations to the adjoining strata," Mr. A. Somervell put forward the view that the intrusion of the granite in question took place after the folding of the Lower Culm strata, but before the Upper Culm series was deposited. In the discussion, while the importance of Mr. Somervell's conclusions was acknowledged, the speakers generally expressed themselves unable to form an opinion until the fuller details of the sections on which the author based his views should be published.

The first paper taken on Monday was that of Mr. R. Etheridge, on "The relation and extension of the Franco-Belgian Coal-field to that of Kent and Somerset." After reviewing the history of the discovery of coal at the Dover boring, where it is expected that the Coal Measures will shortly be reached by the shafts now being sunk, Mr. Etheridge proceeded to discuss the general bearing of this discovery and the probable extension of the southern coal fields under the Secondary rocks. A new section recently obtained by a deep exploratory boring at Abberley, near Ashford, was then described, where after passing through Lower Greensand, Wealden, Portlandian, Kimmeridge Clay, Corallian, Oxford Clay, Lower Gault, and Middle and Lower Lias, red conglomerates believed by the author to be Old Red Sandstone have been encountered at a depth of 1875 feet from the surface. The Jurassic strata in this section are about 450 feet thicker than at Dover. In the discussion on this important paper, Prof. Boyd Dawkins and Mr. W. Whitaker both expressed doubts whether the Old Red Sandstone age of the lowest portion of the Abberley section could be considered sufficiently established; and the former speaker stated that he fully expected some of the Kentish borings would draw a blank, but others would succeed, and all would supply valuable in-

formation. Sir John Evans called attention to the fact that in one section in Belgium, where the Palaeozoic strata were extremely folded, Coal Measures had been met with beneath a wedge of Old Red. Mr. E. Wehner suggested that the Coal Measures showed a tendency to become less and less productive when traced eastward from the South Wales basin; and Prof. Lous asked how the supposed horizontalization of the Dover Coal Measures could be explained, while in their supposed prolongation in Belgium they were so greatly disturbed. Mr. Etheridge, in concluding the discussion, thought there could be no doubt that the bottom rock at Brabourne was Old Red Sandstone, and remarked on the evidence now forthcoming for the continuous underground extension of this formation from Bristol across the south of England, under London and parts of Kent, into Belgium.

The next paper was that of Dr. Marsden Manson, of Sacramento, Cal., on "The laws of climatic evolution"—a highly speculative attempt to explain the Glacial Period as a critical and unique stage in the evolution of this and other planets when the climate passed from "internal" to "external" control. According to Dr. Manson, the climatic conditions of all times preceding the Glacial Period were determined by planetary heat, and were independent of latitude; but the destruction of the continuous cloud-envelope, through the loss of the planetary heat by which it had been sustained, brought about a new set of conditions. After a Glacial Period, due to the more rapid cooling of the land than the sea, a gradual rise of temperature along with a zonal distribution of climate would occur, through the trapping of solar heat by the lower layers of the atmosphere. This latest of the many ingenious attempts which have been made, on both sides of the Atlantic, to explain the Glacial Period, was admirably presented by the author to a large audience, but was subjected to severe criticism in the discussion, the general feeling being that such speculations scarcely fell within the scope of Section C.

Prof. E. Hull brought before the meeting a wide subject of more tangible character, in a paper on "The suboceanic physical features of the North Atlantic." By tracing out the depth-contours of the Admiralty Charts, Prof. Hull showed that the British and continental submarine platform breaks off abruptly in a "Grand Escarpment" at depths varying from 100 to 20 fathoms. This escarpment, from 6000 to 7000 feet high, is, according to Prof. Hull, indented by deep bays and old river-channels, the latter, almost cañon like in places, often prolongations of the river valleys of the existing land. These and other submarine features lead him to agree with Spencer and Upham that the whole area of the North Atlantic to a depth of 10,000 feet was a land surface at a very recent period, and that the conditions of the Glacial Epoch may be thus explained. This paper was followed by another on the same subject by the President of the Section, in which it was shown that the exaggeration of the vertical scale made Prof. Hull's diagrams misleading as to the slopes of the supposed escarpments and submerged river-valleys; and evidence was adduced to prove that extensive earth movements were frequently in progress on the edge of the continental platform. Hence, it was urged, the features to which Prof. Hull had called attention might possibly be due to subterranean causes, a view which was shared by several speakers in the subsequent debate.

On the subject of earth movement, Prof. J. Milne presented the report of the Committee for Seismological Investigation, and Mr. R. D. Oldham, of the Geological Survey of India, gave a lucid description, illustrated by lantern slides, of the Great Indian Earthquake of 1897. The surface indications of faulting and overthrusting which characterised this earthquake were very clearly demonstrated.

At the opening of Tuesday's meeting the President, in exhibiting a portrait of the late E. Wilson, referred feelingly to the loss which geological science had sustained by Mr. Wilson's untimely death, and other speakers bore testimony to his painstaking and self-denying services to the Bristol Museum.

On behalf of Prof. H. F. Osborn, who had expected to attend the meeting but was at the last moment prevented, an exhibit was made of some beautiful water-colour drawings of restorations of *Brontosaurus*, *Phacodus*, and other extinct vertebrates, executed by Mr. C. Knight for the Museum of Natural History of New York. A brisk discussion sprang up, in which Prof. H. G. Seeley, Prof. O. C. Marsh, Sir John Evans, Prof. W. Boyd Dawkins, Prof. W. J. Sollas, and others took part, as to the advisableness of giving reins to the imagination

in the production of these restorations, upon which point widely diverse opinions were expressed.

There was scarcely sufficient time at this meeting to do justice to the carefully prepared paper by Mr. W. H. Wheeler on "The action of waves and tides on the movement of material on the Sea-coast." It was shown by Mr. Wheeler that the travel of shingle is not usually coincident with the prevailing winds, but is in the direction of the flood-tide, and is mainly due to wavelets set up by tidal action, whose total kinetic energy is very large.

Among the other papers brought before the Section were the following on cave exploration: by Mr. H. Bolton and the late E. Wilson, on the exploration of two caves at Uphill, Weston-super-Mare; by Rev. G. C. H. Pollen, on further exploration of the Ty Newydd Caves; by Mr. T. Plunkett, on further exploration of the Fermanagh Caves; and the Report of the Committee on the fauna of caves near Singapore. Mr. P. M. C. Kermode, in the Report of the Committee for investigating the mode of occurrence of the Irish Elk in the Isle of Man, announced the discovery of a large and nearly complete skeleton of that animal near Peel. Mr. J. Lomas brought forward evidence in favour of the occurrence of worked flints in the Glacial deposits of Cheshire and the Isle of Man, but it was felt that further research was necessary before the author could be considered to have established his case. Mr. C. W. Andrews gave an account of the discovery of a portion of the skeleton of a huge Dinosaur in the Oxford Clay of Northampton. Papers were also contributed by Mr. J. K. Dakyns on the probable source of the upper Pelutic lava of Snowdon, by Mr. H. B. Woodward on arborescent Carboniferous Limestone from near Bristol; and by Mr. W. L. Addison and Mr. L. J. Spencer on crystallographic and mineralogical subjects. Several of the Reports of Committees possessed matter of much interest, especially that presented by Prof. A. P. Coleman on the Interglacial deposits near Toronto (where fresh facts of importance have been gained by excavations), and that of Prof. P. F. Kendall on Erratic Blocks, while the Committee for collecting Geological Photographs, that on Fossil Phyllopora, and that on Latic zones in British Carboniferous rocks were all able to report steady progress in their investigations. New committees were formed and grants obtained to investigate the caves at Uphill and Ty Newydd, and an already mentioned committee to take photographic and other records of the Moel Tryfaen section, and most of the old committees connected with this Section were re-appointed.

PHOSPHORESCENCE.

IT is not possible in one lecture on phosphorescence to give any historical sketch which shall do justice to the work of those who have made a study of the phenomena. In a list of the names of the many who have enriched the subject with facts and with theories, those of Becquerel, of Stokes, and of Crookes stand out most prominently. Any attempt to make a sketch of our knowledge of phosphorescence and fluorescence must be to a very large extent an adaptation of the work and of the views of these masters.

The phenomena themselves may be divided into two main classes—those in which the evolution of light is associated with chemical change, and those in which there is no evidence of such direct alteration. In the first class the commonest instances are connected with the process of oxidation. Examples of this kind are numerous. It is hardly possible to take any very easily oxidisable substance and to fail to get some evolution of light. Phosphorus, sodium and potassium, ether, many aldehydes, and a host of organic compounds may be cited as instances. The experimental illustrations of these are not, however, suited to an audience of more than a very few. The same may be said of the examples of animal and vegetable phosphorescence. It is proposed, therefore, to deal more especially with the second class, and to limit the experiments to the cases where the light given out is visible and not of such a character as to necessitate the use of a photographic plate. This evolution of light may occur in varying conditions. In instances such as solutions of quinine and fluorescein and many solids, of which thallene is a good example, the duration of the phosphorescence is so short that it may be said to last only while

1 A discourse delivered before the British Association on September 17, by Mr. Herbert Jackson.

light is acting. Balmann's luminous paint is an illustration of the persistence of the phosphorescent light. With many minerals, notably some fluorapars and felsapars, light is given out when they are slightly heated, or in some cases only crushed.

The most brilliant phenomena are those which can be studied when many bodies are excited with electric discharges inside a Crookes' vacuum tube, while outside of a slight modification of his focus tube fairly brilliant phosphorescence can be obtained by the action of Röntgen rays upon several substances, notably upon some of the platinoxyanides.

In dealing with the whole subject of phosphorescence with the view of attempting to connect all the various phenomena together, it is convenient to divide it into—the nature of the substance giving out the light, the nature of the light given out, and the nature of the exciting causes.

With regard to the nature of the substance, either very much or little might be said, very much from the details of numerous experiments with a great number of compounds, but little from the point of view of general principle. The most important question in this respect is probably the question of the relation of phosphorescence to the purity of the substance giving out the light. Experiments with carefully prepared compounds of many metals make it clear that not a few substances can be made to exhibit phosphorescence when they are so free from impurities that none can be detected by any analytical methods. In some cases, however, there is either no light given out under any of the conditions for exciting phosphorescence, or the light is so feeble that it is necessary to add impurities so as to obtain a suitable molecular condition for rendering a substance responsive to excitement. That the light given out is not to be ascribed to the impurity has been determined by many experiments with varying impurities and careful examination with the spectroscopic. The further consideration of these physical and chemical conditions is better left until the other two aspects of the subject have been dealt with.

If a large number of observations be made of the phosphorescent lights given out by compounds of such metals, for example, as sodium, potassium, calcium, strontium and barium, magnesium and aluminium, it is hardly possible to avoid coming to the conclusion that the colours of these lights have a close resemblance to the colours of the lines and bands seen in the various spectra of the different metals and some of their compounds. Examination by the spectroscopic confirms this conclusion in several instances. It is not suggested that the lines of the metals and the bands of their compounds are reproduced in the spectra of the phosphorescent lights. What is noticeable is that the maxima of light are grouped about these bands and lines, fading away from them and extending to other parts, so that a more or less continuous spectrum is seen with positions of greatest brilliancy. In the case of some specimens of lime these positions are well defined, and in some kinds of fluorapars the green and some red bands are well seen, either when the fluorapars is heated or when it is excited by discharge in vacuum. The questions of exact coincidence and of the shifting of the positions of the maxima of brightness seen with different compounds of the same metal need not be considered here. The intention is only to emphasise the similarity between the phosphorescent spectra of several metallic compounds and the spectra of these compounds, or of the metals in them, obtained in other ways.

In experimenting with phosphorescent compounds it is frequently noticed that specimens of the same substance in apparently the same state of purity give different colours. Confining attention for the present to lime, as a very infusible substance easily obtained in a state of purity, what follows will be made clearer by a brief consideration of the spectrum of the coloured flame produced by holding some compound of calcium, *e.g.* calcium chloride, in the flame of a bunsen burner.

The spectroscopic breaks this red flame up into red, orange and green bands and a blue line. For the moment the suggestion may be taken that these differently coloured bands are indications of the existence in the flame of groups of particles of calcium compounds of varying degrees of complexity—the red being related to more complex groups, the orange to less, and so on. It seemed not unlikely that it might be possible by preparing lime from a great many calcium salts to obtain separate specimens which might preserve in the solid state some relation in their own molecular complexity to that of the salts from which they were obtained, or the conditions of decomposition

of the different calcium salts might impress upon the residual limes different characters of molecular structure. The preparation of about 350 specimens of lime showed that it was quite possible to get specimens some which phosphoresced red, some orange-red, some orange, others green, and some blue. Examination of their phosphorescent lights with the spectroscopic showed, as referred to before, that the maxima of brilliancy in their spectra were grouped about the bands and lines of the usual spectrum of calcium oxide. The details of the preparation of these specimens of lime are too elaborate to enter into here, nor is it possible to do more than just to refer to their varying densities and different rates of hygroscopicity. Out of the number of specimens tried the most satisfactory were analysed to make sure that it was really lime and only lime which was being dealt with in each case. In general terms it may be said that the most complicated organic salts of calcium yielded the best attempts at lime giving blue phosphorescence, simpler bodies gave green, while the best orange was obtained from Iceland spar, and the red from specially prepared calcium carbonate. That lime yielding a blue colour was obtained from highly complicated organic salts does not contradict the former suggestion that perhaps it is really of simpler molecular structure than the others. Chemists are familiar with the conception that the complexity in structure arising from the massing of many molecules together in groups is probably often greater in bodies of apparently simple chemical composition than in those of a much more highly complicated nature.

The colours seen in the specimens of lime shown are not pure. In each one the other colours are present; thus the orange contains also the red, green and blue, only these are masked by the greater proportion of the one colour. Compare for example the light obtained from a vacuum tube containing the gas helium. In this case the colour is yellow, although the spectrum contains beautiful red, green and blue lines. If the different colours are related to varying molecular complexity in the substances, then it might be said that the lime showing a green light contains a large proportion of groupings of such a nature as to be capable of oscillating in a way to give rise to green light, and in like manner for the red, orange and blue specimens. Whether it will be possible or is in the nature of lime to separate out the different kinds in a state of purity can only be decided by further experiment.

The examples of different forms of lime have been so far exhibited only under the conditions obtaining in a high vacuum with an electric discharge. Before trying to show the points in common between these phenomena and the phenomena of phosphorescence in other conditions, it may be as well to consider briefly the character of the action in a high vacuum. The suggestion which follows is not intended to be anything but an imperfect attempt to bring all the phenomena of phosphorescence into line with one another.

When a discharge passes through a vacuum there can be little doubt that the transferring medium is the residuum of gas in that partial vacuum. If the particles of this gas behave as visible masses are seen to do, they are probably attracted or are driven to the electrode, which is at high potential. Receiving the same kind of charge as this electrode, they fly off from it in that charged condition.

But if these conditions consist of more than one unit, each unit, after the group has travelled a certain distance from the electrode, must repel each other unit in the same way as the whole little group was repelled from the electrode. If, however, the units making up the group are held together by that something which is called chemical attraction, a condition of strain is set up in which the electrical repulsion is striving to overcome the chemical attraction. Travelling unimpeded through the high vacuum this condition of strain would be maintained until the charged group met with something capable of discharging it. At that moment of discharge the chemical attraction would assert itself, there would be a rushing together of the units composing the group, and an over-rushing, whereby oscillations would be set up. These oscillations, considered as blows or pulses, either directly or ethereally transferred to a substance, would set it in turn oscillating in a manner fitted to its own molecular structure, and its oscillations would in their turn give rise to the undulations which appeal to our eyes as the phosphorescent light. If instead of the discharge taking place on a substance capable of responding to and absorbing most of the energy of the consequent oscillations, it were to occur on glass, platinum, or any of the materials which have been

employed, it is conceivable that the oscillations would appear as short ethereal waves or, in other words, Röntgen rays. In the case of a low vacuum, or of no vacuum at all, the charged particles would discharge themselves against the intervening gas, which would in its turn respond to the rapid oscillation and give out its own particular coloured light. The expression "short ethereal waves" is used intentionally, for if there should be forthcoming experimental evidence of the complex molecular structure of a gas, it is reasonable to suppose that in a high vacuum, with consequently a high potential at the electrode, the internal electrical repulsion in a group would tend to a dissociation resulting finally in the simplest form of system capable of separate existence in those conditions. It might be expected that the oscillation frequency of so simple a system would be very high.

Here it may be stated that this comes to practically the same thing as Sir William Crookes' original conception of radiant matter.

Leaving the method of electrical excitation in vacuo for obtaining phosphorescence we may now turn to light as a source of oscillations. For the sake of simplicity it will be best to continue the experiments with the same substance, viz lime. If this body be exposed to the light of the sun, of the electric arc, of a hydrogen flame, and of a great many other substances in a state of vigorous combustion, a phosphorescent effect is obtained, feeble in comparison with the results in vacuo, but apparently similar in kind. The best light for inducing the phosphorescence is the spark from a fairly powerful coil with a Leyden jar in circuit. Many specimens of lime go on giving out light for a considerable time after exposure. A cylinder of lime such as is used in the production of the lime light glows quite visibly when it is rotated before a jar-spark.

The light from the sun is not so active in inducing this glow, but with suitable arrangements a fairly visible result can be obtained. The colour of the glow from most lime made from limonite is an orange-red becoming a golden orange when the lime is heated. The introduction of glass, mica or Iceland spar between the spark and the lime, cuts off the glow at once, since these bodies are opaque to the undulations to which lime of this kind responds. Quartz, rock salt, and selenite are quite transparent.

It is found that the different forms of lime which have already been exhibited in vacuum tubes yield, when exposed to the jar-spark their specially coloured phosphorescent glows. But these are difficult to see, they are very faint when pure specimens of lime are used. However, there is a way out of the difficulty. The faint light scarcely visible at the ordinary temperature may be increased very considerably by raising the temperature. As an extreme instance of this a specimen of calcium sulphide may be taken. After exposure to almost any source of white light this glows with a bluish phosphorescence which becomes quite brilliant when the sulphide is heated. A similar change is noticeable in the case of the different limes. The orange, green and blue varieties exposed to a series of jar-sparks, and subsequently dusted over hot plates, give with easy visibility the colours which they exhibited in the vacuum tubes and which may, for the present, be considered as sensible indications of their molecular constitutions.

Two important considerations have to be dealt with at this point. In the first place the question arises how far one and the same light, *viz* one and the same oscillation frequency, will excite the different specimens of lime. Without entering into dry numerical details, it is not possible to give a complete answer to this question. In a general sense, however, it is apparently true that, although the range of frequency is large, the red and orange varieties of lime respond to oscillations less rapid than those which readily affect the varieties giving a green or blue phosphorescence. It is possible to obtain a form of lime which illustrates this experimentally. It is not easy to make. It is prepared from calcium urate by heating this for many hours to a dull red heat, and afterwards raising the temperature of the blackened mass sufficiently to burn off all the organic matter and leave only lime. The residue on analysis was shown to be really lime. Such a specimen exposed freely to jar-sparks, and afterwards heated, shows mainly an orange phosphorescence; but if glass or mica or Iceland spar be placed between the lime and the source of light, then the effect of heat is to intensify greatly a phosphorescence of a blue colour. It must be clearly understood that this blue was there before, only masked by the superior brilliancy of the orange colour; the undulations which

would otherwise have affected the molecular groupings, capable of giving out the orange light being cut off by the glass or mica. It would be tedious to give all the reasons for assuming that the oscillations exciting the blue phosphorescence are probably the more rapid. To some extent the transparency of glass and mica to X-rays may be taken as confirmatory; but to follow the argument out from spectroscopic evidence and measurements would involve a discussion unsuited to a lecture dealing with general questions. Referring, however, to the suggested explanation of the action taking place in a vacuum tube, it is not inappropriate to mention now that it is possible to make a specimen of lime give an orange glow in a moderate vacuum while a portion of the same specimen is exhibiting a blue glow in a high vacuum. The readiness with which this blue glow appears, and the time which it takes to develop, must be taken into account in dealing with its supposed origin, and with its relevancy with the question of the relation of the rapidity of the exciting undulation to the wave-length, *viz* to the colour, of the phosphorescent light. Perhaps it is advisable to leave this point for the moment, and to turn to the second consideration. This deals with the question of the duration of the phosphorescence.

At the beginning it was shown that some bodies glow only while light is acting upon them, while others are under the direct influence of an electric discharge. In others there was a marked after-glow, while still others required the application of heat before any phosphorescence was visible, or, as in the case of the limes, before the phosphorescence was easily visible. With Balmain's luminous paint, or with any body which gives a marked phosphorescence that lasts for some time after withdrawal from the exciting influence, it can be readily shown that lowering the temperature reduces the brilliancy of the glow, but lengthens the time during which it lasts. The effect of heat has already been mentioned as vastly increasing the brilliancy, but it greatly diminishes the duration of the light. On the other hand, Prof. Dewar has shown that great reduction of the temperature will cause the phosphorescence to linger for a considerable time in many substances which had hitherto been considered as practically non-phosphorescent. The different behaviours of substances in this respect can, perhaps, be best brought under one explanation by applying the idea of a statical charge or a duration of strain to the phosphorescent substances. Duration of phosphorescence would then be a measure of rapidity of discharge. If it be supposed that, the strain having been set up in the particles of a substance, these discharge themselves against one another, or rather against uncharged particles, then a substance with great freedom of transference of movement among its particles would fail to show any sign of phosphorescence, since the strain would be released or conducted away by rapid transference before a condition could be set up, out of which oscillations of sufficient amplitude could arise. With rather less freedom of movement among the particles the non-conducting state might be reached by restricting the extent of that movement by cold, as in Prof. Dewar's experiment. Still less freedom of interchange may be considered to obtain in Balmain's luminous paint, and even less in the limes, which require heating to show up their phosphorescence; while, in the case of the chlorophane and many other minerals, the condition of strain, however set up, can apparently be retained indefinitely. Specimens of lime after exposure to the jar-spark have been found to give out light when heated after being four years in the dark.

It seems not altogether improbable that the influence of impurities in promoting phosphorescence may often be attributed to their interfering with the freedom of movement, and so permitting the groupings of the substance to be sufficiently highly charged. The effect of heat in rendering a substance a better conductor can be well studied with pure substances in vacuo under the electric discharge.

Under the vigorous bombardment of radiant matter the temperature of the substance rises. In some substances this leads to an increase in the brilliancy of the glow maintained often even when the heating is very considerable, in others the hotter portions are marked out by a complete absence of phosphorescence. Observation seems to favour the conjecture that this absence is in many cases to be explained on the hypothesis that the heat endows the molecules with such freedom as to practically render them unstrained. To pursue this part of the subject any further would lead to a discussion of a question that can only be referred to. It is the consideration of how far the change of glow in some specimens of lime from a red or orange

colour in a low vacuum to a green or blue glow in a high vacuum is to be attributed to shorter oscillations in the exciting cause, and how far the change is connected with a dissociation of complex groupings into simpler ones; a dissociation which may be considered to be brought about by the rapid oscillations breaking up the lime groups into two or more smaller groups. Connected with this is also the question dealing with the possibility of phosphorescence being coincident with the recombination of the separated smaller grouping; but this part of the subject can only be illustrated by experiments of too minute a character to be suitable to a lecture, and involves besides the study of too many details. One other thing which must be taken into account in drawing any deductions from the change in the colour of the glow as the temperature rises is that in some cases the effect of heat is to discharge some colours in a complicated substance, and so leave visible others which were before masked.

The whole question of the inter-relations of the molecular weights of the phosphorescent substances, of the wave lengths of the exciting undulations, and of the wave-lengths of the resulting glows is an important and interesting one; but it must be left alone in the present lecture with the statement, somewhat unsatisfactory it is feared, that, while there is no doubt that special undulations of measurable wave-length are most efficient in exciting phosphorescence in some substances, the same effects can be produced, though to a less degree, by vibrations which can perhaps be best described as undifferentiated and irregular pulses.

Returning to the sources of oscillations, there is one other source which has yet to be considered, and that is chemical combination. The fact that many substances will phosphoresce during and after exposure to the flame of hydrogen has already been alluded to. The flame of coal gas burnt in a Bunsen burner will excite phosphorescence in many specimens of lime, but the effect is not strong enough to be shown to an audience.

Naturally this effect would be stronger the nearer the lime was placed to the source of light. Inside the flame itself would be the nearest attainable position, but then the heating effect practically masks or destroys all others. In phenomena such as the glow of phosphorus the temperature does not rise to any very marked extent. It is possible to obtain chemical combination in the presence of many bodies of a porous nature without, during the early stages of the action, getting very marked heating effects. The action of sodium platinum in inducing the oxidation of coal gas or alcohol vapour may be taken as a familiar illustration of the use of a porous material for this purpose.

In the case of a conducting metal it could not be expected that the oscillations arising from the chemical combination would cause phosphorescence even in the early stages, when the temperature has not risen to any extent, but if such a body as lime could be obtained in a very porous condition it might, while acting as an inducer of chemical combination, itself respond to the oscillations arising out of that combination.

This is found to be the case. A jet of unlighted coal gas allowed to play over warm porous lime produces a slight phosphorescence, very faint, but quite visible in a dark room.

By dusting easily volatile substances, such as finely powdered resin, over slightly heated lime, the oxidisable vapour is brought more closely into contact with the lime, and the phenomenon of phosphorescence is made more visible. So far, however, it has not been obtained with sufficient brilliancy to be shown to more than a few people at a time. When the different limes that have already been experimented with are subjected to oscillations from this chemical source, they yield their respective colours in the same way as before. The lime, which showed a green glow in the vacuum tube, or when dusted on to a hot plate after exposure to the jar-spark, gives a green glow with the powdered resin. So also in the cases of the orange and blue yielding limes. The possibility of the phosphorescence being due to the resin vapour itself is excluded by control experiments with other porous bodies which do not phosphoresce, but yet are equally active in bringing about oxidation.

This phosphorescence was often well seen when some of the limes were being prepared in a furnace (It has been already mentioned that many substances retain the power of phosphorescing at a high temperature, especially if they are in a very fine state of division or not quite pure.) Most of the limes were made from organic salts of calcium, and as the organic matter burnt away, a thin and scarcely visible flame played

over the surface of the lime at the top of the crucible in which the calcination was carried out. It was frequently quite possible to predict by watching the glow which was developed in the lime what colour would be given by the lime when phosphorescent was brought about by oscillations from the other sources, such as the jar-spark or the discharge in vacuo.

No one who has spent much time in experimenting with various substitutes for lime in lantern work can have failed to be struck by the very different appearances of the light on the screen given by such bodies as magnesia and arconia in comparison with lime, but, perhaps, the best examples are the two mantles in use at the present day for incandescent gas lights. One of them, the Welsbach mantle, gives a light of almost a white colour. The other, or Sunlight mantle, shows a much pinker colour to the eye.

Experiments with many substances used in a similar way to the mantles seem to indicate that, in addition to the ordinary heating effect of the gas flame, there is another and a phosphorescent effect which probably, so far as observation can tell, precedes the ordinary hot stage. It is not usual to find any pure substances capable of showing this phenomenon to any marked extent unless, as mentioned just now, they are in an extremely fine state of division, a condition which, in the presence of impurities, may be considered to be unfavourable to the too rapid discharge of the strained particles, thus giving them the opportunity of becoming fully enough charged to make their oscillations, when they are discharged, of sufficient vigour to be sensibly visible.

If either of the mantles mentioned be introduced into a tube and treated with an electric discharge in a high vacuum, the phosphorescent glow can be studied either with or without the heating effect. The glow of the Welsbach mantle is a greenish white, but not very marked. The Sunlight mantle gives a fine red glow. It is interesting to note that the glow shows great persistence even when the temperature of the substance has been raised very considerably by the vigour of the bombardment.

Having now dealt with the last source of oscillation which it was proposed to consider, it may be as well to summarise the conclusions which for the present seem to be the least open to objection so far as experimental evidence goes. The attempt has been made to connect together all the phenomena of phosphorescence with a view of showing between them a likeness in kind. Any theoretical suggestions should be taken only as hypotheses for assisting this attempt and for pointing the direction of further experiments. It is believed, then, that the following typical examples of the various phenomena which are described as phosphorescent phenomena are similar in kind and can be related to one another by the application of slight modifications of the same general principle—the glow of phosphorus, the fluorescence of quinine, the sparking of heated chlorophane, the luminosity of Balmann's point, the light from lime in a vacuum tube, and the glowing of barium platocyanide under the influence of X-rays. To these it is proposed to add coloured flames and the spectral light of glowing gases. It is suggested that all these phenomena may be looked upon as outward evidences of response on the part of the substances to rapid oscillations, whether these oscillations have their origin in chemical combination in what is commonly spoken of as light, or in electrical discharge. The nature of that response may in some cases be of a direct character; but, when account is taken of the many degrees of persistence of phosphorescence and of potential phosphorescence, it seems in many cases first to assume the form of something which, to avoid circumlocution, may be called a statical charge. The release of this condition of strain is accompanied by oscillations which give rise to the visible undulations of the phosphorescent light.

One final suggestion may perhaps be made, though it is mentioned with diffidence, as many may consider it outside of the subject.

If it be accepted that the light of the sun has its immediate origin mainly in the masses of luminous clouds floating in the photosphere, and if these clouds be considered as condensations into material of greater molecular complexity than that from which they were condensed, then it may be not altogether out of place in the present lecture to speculate on the relation between the actual light from the glowing clouds and possible oscillations of the particles of the medium in which they exist. There is no need to emphasise the idea that the oscillations of very simple molecular systems give rise to undulations which can only be perceived when, by their action upon something

more complex than themselves, they cause either a distinct chemical change or set up undulations within the range of the visible spectrum.

May it be that there are similar oscillations in the sun, that the simpler materials out of which the photospheric clouds are condensed vibrate too quickly to give out visible light, but that their oscillations are rendered visible when they are absorbed and responded to by the more complex groupings of the condensed masses? A sun-spot, looked upon as a partial absence of clouds, would mean that the conditions which serve to screen us to a great extent from the rapid undulations have been somewhat modified.

It is too much to suppose, in view of the close resemblances between many of the actions of light and electricity, and of the well-known electrical effects of ultra-violet light and of X-rays, that the breaking down of a dielectric which they can accomplish may, on a vastly larger scale, accompany an unusual exposure of the earth to similarly rapid undulations? Should there be anything in this suggestion, it may help to remove a part of the difficulty in relating the presence of sun spots to those casual electrical disturbances with which they undoubtedly coincide in point of time.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

A NEW technical institute was opened at Wellesborough on Thursday last, by Sir Philip Magnus. The building has been erected by the Urban District Council at a cost of 3000*l.*, exclusive of the site, and it will be maintained out of the free library rate.

THE following donations are announced in *Science*.—Colonel Oliver W. Payne has given 1,500,000 dollars to the Cornell University Medical College, the late Mr. Rowland Hazard has bequeathed 100,000 dollars to Brown University; Mr. George A. Gardner has given 20,000 dollars to the Massachusetts Institute of Technology, to be added to the general endowment fund. Dr. D. C. Parsons, of Chicago, has offered 50,000 dollars to Fairmount College, Wichita, Kans., on condition that 150,000 dollars can be raised; in connection with the Maryland Agricultural Experiment Station, the State Legislature has granted 14,000 dollars for the erection of a science hall, to be used jointly by the college and station. 10,000 dollars have also been granted for inaugurating State work in entomology and vegetable pathology, and an annual grant of 8000 dollars for maintenance has been made.

THE new Technical Institute and Public Library, erected by the West Ham Corporation, will be opened to day by Mr. J. Passmore Edwards. The foundation-stone of a natural history museum, which will be built close by, will also be laid. The Technical Institute, the principal of which is Mr. A. E. Bruce, will be wholly under the control of the municipality, and will be financed from municipal sources. Every department is well equipped, special attention being paid to the chemical laboratories and the engineering workshops. The buildings have cost 450,000*l.*, and a further 15,000*l.* has been spent on equipment and fittings. The money for the working has been created by the accumulation of the Excise duties grants, but the corporation have secured sanction to raise 35,000*l.*, and have power to levy a 1*d.* rate (which will produce about 3800*l.*) for technical instruction purposes. The new central library is wholly on the ground floor, and is fitted with all the modern appliances of such institutions. Towards the cost of the natural history museum Mr. Passmore Edwards has contributed 2500*l.* The Essex Field Club, who will have the scientific control of the museum, will house their large collection here.

IN the course of an address upon "Science and Education," delivered at Mason College on Tuesday, Sir Archibald Geikie remarked that there is no more pernicious doctrine than that which measures the commercial value of science by its immediate practical usefulness, and restricts its place in education to those only of its subdivisions which are of service to the industries of the present time. By all means let artisans know as much as could be taught them regarding the nature and laws of the scientific processes in which they are engaged. But it is not by mere technical instruction that the industrial and commercial greatness of the country will be maintained and extended. If

we are not only to hold our own, but to widen the boundaries of applied science, to perfect our manufactures, and to bring new departments of nature into the service of man, it is by broad, thorough, untrammelled scientific research that the success must be achieved. The continued development of the faculty of prompt and accurate observation is a task on which students cannot bestow too much attention. Amongst the mental habits which education in science helps to foster are a few which specially deserve attention as worthy of most sedulous care all through life. In the first place should be put accuracy, in the next thoroughness, which is closely akin to accuracy, then breadth, then the habit of wide reading in scientific literature; and then patience. It is by failures as well as by successes that the true ideal of the man of science is reached.

THE following entrance and other scholarships have been awarded at London Medical Schools.—London Hospital Medical College. Price Scholarship, value 120*l.*; Mr. F. W. Jones; Epson Scholarship, value 125*l.*; Mr. C. Colmer; Prince University Scholarship, value 60*l.*; Mr. Bousfield, Science Scholarship, value 60*l.*; Mr. J. W. Fox; Science Scholarship, value 30*l.*; Mr. Rainforth.—Charing cross Hospital Medical School. Livingstone Scholarship (100 guineas) to Mr. G. L. Bellamy; Huxley Scholarship (55 guineas) to Mr. B. K. Bickford; Universities Scholarships (each 60 guineas) to Mr. H. G. Gabb and Mr. B. G. Fiddian. Entrance scholarships have also been awarded to Mr. R. H. Cooper (60 guineas), Mr. J. M. Davies (40 guineas), and Mr. T. Law (30 guineas), and exhibitions of 30 guineas each to Mr. A. C. Ingram, Mr. G. O. Lambert, and Mr. B. K. Lloyd.—Guy's Hospital Medical School. Scholarships for University students: H. S. French, Christ Church, Oxford, 50*l.*; Open Science Scholarship, E. H. B. Milson, Guy's Hospital Medical School, 150*l.*; F. Rogerson, Guy's Hospital Medical School, and N. J. Spriggs, private study (equal), 30*l.* each.—St. Thomas's Hospital Medical School. Entrance Scholarships in Natural Sciences: 150*l.*, Chas. Michael Roberts, 60*l.*, Harry Mellor Woodcock, 20*l.*, Charles Hugh Latham—University College, London. Medical Entrance Scholarships: 131 guineas, Mr. H. A. Haig, 55 guineas, Mr. M. Stewart Smith, 55 guineas, Mr. W. M. Sadler.—The first and second entrance scholarships of the Middlesex Hospital Medical School have been awarded to Mr. W. Cameron Macaulay and Mr. William Gordon Taylor, respectively.

THE Secondary Education Bill introduced into the House of Commons by Colonel Lockwood, proposes to separate technical from secondary education. For this and other reasons the Council of the Association of Technical Institutions has entered a protest against the Bill. It is pointed out that the proposed separation of technical and secondary education is an entire reversal of previous educational policy, and if it were carried into effect it would be detrimental to the education of this country. The power which Colonel Lockwood's Bill gives for the creation of a new local authority to deal specially with secondary education is also objected to, the multiplication of local authorities for the purposes of education beyond the elementary stage being regarded as a retrograde step. Other defects which the Bill possesses are: (1) The proposal to provide for the financial needs of secondary education by taking away from technical education part of the money assigned for instruction in science and art, and part of the money available under the Local Taxation Act. (2) The proposal that the limits of secondary and technical education shall be settled on the basis of the opinions expressed by an advisory Council on which secondary schools and teachers shall be very largely represented, but which shall not contain a single representative of technical institutions. (3) No provision is made for the registration of teachers in technical institutions. (4) The proposal that a local secondary education authority shall not provide or have the management of any secondary school. The Council desires that steps should speedily be taken to organise secondary education in this country, and is willing to aid any statesmanlike attempt to accomplish this, but Colonel Lockwood's Bill would, it is pointed out, do mischief by creating a distinction between technical and secondary education, and setting up a purely artificial barrier between the two. It is not expected that the Bill will pass, but as the manner in which it is received may influence the Government to incorporate the proposals contained in it in the Secondary Education Bill to be presented next session, it behooves those interested in technical education to show unmistakably that such provisions as those in Colonel Lockwood's Bill are not generally acceptable.

At a Congregation of Cambridge University held on Saturday, Dr. Hill, the retiring Vice-Chancellor, delivered a valedictory address, in the course of which he made the following remarks:—"The admirable and central sites which have been purchased by the University during the last three years are still entirely unoccupied, although many departments of the University are either overcrowded or most inadequately housed; but, at the desire of our Chancellor, steps have been taken which may, it is hoped, bring in the funds necessary for the erection of the buildings which are so urgently required. A very influential committee of University men has been formed for the purpose of organising a 'Cambridge University Association,' the members of which will be kept informed of, and will be pledged to make known, the needs of the University. It is hoped that through the influence of this association the University may be placed in possession of the means of maintaining her position in the ever widening and ever changing educational life of the nation. The legal and medical schools, feeling that it is impossible to wait until the general resources of the University allow of the provision of new buildings, have opened subscription lists on their own account, and it is significant of their sense of the pressing need for such accommodation that of the 6000 already subscribed a large proportion has been given by the teachers of law and medicine and other residents in the University. Among gifts to the University during the past year were a very valuable collection of minerals given by the Rev. T. Wiltshire, Professor of Geology and Mineralogy in King's College, London, a collection of polyzoa given by Miss E. C. Jelly, a skeleton of the elephant seal given by Sir W. L. Buller, K.C.M.G., a MS. of *de proprietatibus rerum* of Bartholomaeus Anglicus given by Lieut. Archibald Stirling, and a collection of Malay native objects given by W. W. Skeat. The University has also received a bequest of 10,000*l.* under the will of the late A. W. G. Allen for the establishment of a scholarship or prize in memory of the Right Rev. Joseph Allen, formerly Bishop of Ely, and grandfather of the donor. Not a few gifts for the foundation of scholarships and prizes have been received by the University during recent years. Such gifts are always acceptable, but at the present time there is a greater need for the endowment of teaching posts and the provision of buildings for University purposes than for the encouragement and stimulation of student." Dr. Hill was re-elected Vice-Chancellor for the ensuing year.

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, September 26.—M. van Tieghem in the chair.—On the changes occurring in the large nebula in the belt of Andromeda, by M. G. Rayet. The brilliant point announced by M. Seraphimoff is probably the central point of the nebula, the brightness of which is variable, and is now temporarily increased. The position of the point does not coincide with that of the temporary star whose position was measured by M. Higouard in 1885.—On a geometrical theory of the marine compass, by M. S. L. Ravier.—On the convergence of some *réduites* of the exponential function, by M. H. Pade. The term *réduites* is applied to a function (regular in the neighbourhood of the origin) of the rational functions which, near this point, represent this function with close approximation.—Action of lime and chalk upon certain natural humic materials, by M. G. André. The earths were heated at 100° for fifteen hours with lime, chalk, or water, and determinations made of the nitrogen volatilised as ammonia, the nitrogen rendered soluble, and the ammonia present in the filtrate.—On the composition of coelocosome, by M. A. B. Griffiths. Coelocosome is the name given to a colourless matter, green in acid, purple in alkaline solutions, found in *Coelocoma tenebrarum*.—Chlorophyll assimilation in plants growing by the sea-shore, by M. Ed. Griffon. The leaves of maritime plants under the influence of sea-salt undergo a reduction of chlorophyll, acquiring by way of compensation a greater thickness and a more marked development of the assimilating tissues. But this modification of structure, although having a tendency to compensate the injurious action of the salt, is insufficient, since the assimilation per unit of surface is always less for the leaves of a maritime species than for comparable leaves of the same species growing inland.—Observations of an aurora borealis at Göttingen (Hanover) on September 9, by M. B. Violle.—On an observation of the green ray at sunrise, by M. H. de Maubeuge. The phenomenon was noticed from the steamer *Ernest Simons*, by several people simultaneously, over Mt. Sinai.

THURSDAY, OCTOBER 13, 1898

THE NATIONAL PHYSICAL LABORATORY

THOSE who remember the address by Prof. Lodge at Cardiff, in which he advocated the establishment of a National Physical Laboratory, and the feeling of hopelessness with which the suggestion was received, will be confirmed in the view that the world moves by the fact that a Treasury Commission has now reported in favour of the scheme. Sir Douglas Galton dealt with the question in his presidential address at Ipswich, and, on the following day, read a paper on the Reichsanstalt before Section A. That body then took the matter up in earnest and, even in its so-called decadence, was strong enough to start a movement which was before long supported, with practical unanimity, by all British physicists and chemists. A deputation to Lord Salisbury followed, and a Committee, with Lord Rayleigh as Chairman, was appointed—

"To consider and report upon the desirability of establishing a National Physical Laboratory for the testing and verification of instruments for physical investigation, for the construction and preservation of standards of measurement, and for the systematic determination of physical constants and numerical data useful for scientific and industrial purposes—and to report whether the work of such an institution, if established, could be associated with any testing or standardising work already performed wholly or partly at the public cost."

The Committee asked various scientific and technical institutions to nominate witnesses, and the evidence thus collected was very interesting and almost entirely in favour of the scheme. The views of those who approached the subject primarily as students of pure science are well known to the readers of NATURE, but it is satisfactory to note that they were warmly supported from the practical point of view by such men as Sir Bernhard Samuelson, Sir William Anderson, Sir Lowthian Bell, Mr. Crompton, Mr. Preece and others directly connected with industry and technology. The number of questions suggested as those on which useful work might be done was indeed almost overwhelming, and the Committee lay stress on the fact that one of the chief functions of the Governing Body would be to select the most important of the various problems with which they might deal. We agree with the opinion of the Committee that a strong Governing Body would arrive at a solution of this difficulty.

The Committee had further to consider the relations between the proposed institution, the Standards Department, and the Electrical Standardising Laboratory of the Board of Trade. They wisely decided that the new institution ought not to be under a Government Department, and as the Board of Trade has statutory powers with respect to the standards, this decision precludes a fusion between the Standards Department and the new Laboratory. It is, however, suggested that the relations between the two should be very close, that the Permanent Secretary of the Board of Trade should be *ex officio* a member of the Governing Body, which "should be consulted by the Standards Office and the Electrical Standardising Department of the Board of Trade upon

difficult questions that may arise from time to time or as to proposed modifications or developments."

It is not, however, proposed to found a brand new institution. "In the opinion of the Committee the principles which underlie the proposal for the establishment of a National Physical Laboratory have been tested on a comparatively small scale at the Kew Observatory with the most satisfactory results."

The Committee therefore propose the extension of the Kew Observatory, and as that institution is controlled by the Royal Society it naturally follows that its management when enlarged and developed should remain in the same hands. A considerable change is, however, contemplated in the constitution of the Governing Body. Representatives of industry are to be added, and it is stipulated particularly that these should not necessarily be selected from among the Fellows of the Royal Society.

The plan thus sketched out seems reasonable and practical, and it is to be hoped that the Government will give effect to it.

If it does, and if the Royal Society consent to play the part assigned to it in the Report, the Council will undertake a grave responsibility and enjoy a great opportunity. Much will depend upon the start.

Nothing is said in the report of the Committee as to the funds which would be wanted to carry out the scheme they propose. The form which it ultimately assumes must depend upon whether the Government subvention is large or small. It is, we suppose, improbable that the new institution, if founded, will at first be on the same scale as the Reichsanstalt at Berlin. The question as to whether that institution is not too magnificent has in fact occurred to many of those who have seen it.

No one has ever accused the Kew Observatory of too lordly buildings or too lavish an equipment. As the central thermometric station, it has been hampered by the fact that it has not possessed the apparatus or the means to establish direct comparisons with the gas thermometer. We believe that this difficulty is about to be overcome by the generosity of Sir Andrew Noble who is presenting the necessary installation to the Observatory. But though in this and in other respects it has failed in the past to reach the level of its modern rivals, Kew has been useful both to industry and science. This is proved by its financial success. With a modest endowment of 470*l* a year and the use of a Government building, the Committee make about 2000*l* a year in fees, and the average receipts increased in the last five years about 25 per cent. over those in the earlier half of the decade. If a specific example of its operations be needed, it is sufficient to cite the fact that, unsolicited by the trade, Kew established a system of trials for watches, in which the leading makers now eagerly compete, and which they confess has improved the standard of their work.

The more scientific side of the functions of the Observatory is illustrated both by its magnetic work and by the fact that the Committee is now employing a gentleman to compare the platinum thermometer over a wide range with the gas thermometer at the Bureau des Poids et Mesures at Paris. What is wanted is the multiplication of operations

such as these, together with the systematic determination of selected physical constants. With larger funds such results could be obtained, and there is no reason to fear that with a carefully chosen Committee, a good organisation, and the best Director that can be secured, the National Physical Laboratory would in due time take its place among the great scientific institutions of Europe, and would forge another link in the chain which binds science and industry together.

EXPERIMENTAL PHYSICS.

Lehrbuch der Experimental-Physik. Von Eduard Riecke. Zweiter Band, Magnetismus, Elektrizität, Wärme. (Leipzig Verlag von Veit und Comp., 1896.)

IN NATURE for August 20, 1896, we reviewed the first volume of this work, and there stated what seemed to us to be its most notable features. The second volume strikes us as being even better than the first: the author, at any rate, seems to move in the subjects here treated with still more grace and freedom.

The treatment of the subjects is clear, and, so far as we have seen, always accurate, though the methods adopted are not always the newest. Perhaps, it may be argued, they are none the worse for that. However, in one or two places, there are described at some length various pieces of apparatus which hardly deserve a place in a modern book on electricity. An electrician may, for example, know nothing of the "unit jar," and not be a whit the worse. Yet Prof. Riecke gives "Ein vollständiges Bild von der Konstruktion der Massflasche."

Dielectric action is illustrated by well-chosen and instructive diagrams. The theory described is one precisely analogous to that of magnetic induction and magnetic force, in which the medium is supposed to be made up of polarised molecules, the opposite charges of which act at a distance like other electric charges, while the electric induction is defined as the electrostatic force in a crevasse at right angles to the polarisation, and the electric force as the electrostatic force in a cylindrical hollow along the lines of polarisation. Thus we have in electricity, as in magnetism, the equation

$$\mathcal{E} = \mathcal{G} + 4\pi\mathcal{J}.$$

Here a distinction is drawn between the true and the free distribution on the plate of a condenser, a mode of discussing the external action of the condenser which is supplemented by an all too short account of the Maxwellian view of the subject.

Prof. Riecke gives at p. 23 a simple construction for finding the direction of a magnetic line of force at any point P. Draw to the point a line CP from the centre C of the magnet, and find a point Q such that $CQ = \frac{1}{2}CP$. Draw from Q a perpendicular QR to CP, meeting the magnetic axis in R. RP is the direction of the line of force at P. It ought to be stated in the text that this construction, which is easily derivable from the polar equation $r = c \sin \frac{1}{2}\theta$ of the line of force, is only applicable to the case of an infinitely short magnet; that is, it can only be applied for an ordinary bar magnet when the distance CP is very great in comparison with the length of the magnet.

The subject of electromagnetism is fully dealt with so

far as the magnetic action of a current element, and the mutual force between two current elements are concerned. The law of Laplace (which was also given by Savary and by Ampère) that the magnetic force produced by a current γ in an element C of a circuit of length ds at a point P at distance r from the element and making an angle θ with CP is $\gamma ds \sin \theta / r^2$, and acts at right angles to the plane of the element and P, is first stated and used for the ordinary applications. Then from that, by the principle of action and reaction, is obtained the electromagnetic force on a current element γds in a field of intensity H, making an angle θ with the element is $\gamma H ds \sin \theta$. It is not noticed here, however, that taking the magnetic action of an element of current to be as stated in Laplace's formula, the reaction must exist in the same line as the action, and hence to get the electromagnetic force on each element the reaction must, after the method of Poincaré, be reduced to a force on the element and a couple.

All these laws of action of elements however are, it should be more emphasised, incapable of absolute demonstration. It is impossible to experiment with elements, and so settle the question, and no confirmation obtained by arriving at the observed actions of complete currents is proved in the least, inasmuch as the addition to the action of an element of any term, which integrated round the circuit gave a zero result would give another law, equally valid so far as the evidence goes. The same point requires mention again later when Ampère's law of the mutual action of two currents is discussed. It seems therefore to be demonstrably certain that in the ordinary theory of circuits it is impossible to arrive at a unique law of the mutual action of elements. Yet time is still wasted on the search for it.

Notwithstanding the narrow limits of the book as compared with many other Lehrbücher, Prof. Riecke has succeeded in compressing an immense amount of valuable matter into his chapters on electricity and magnetism. Of course the pages are large and well filled, and there is far more than would be contained in an English book of the same number of pages, but the author has succeeded wonderfully in contriving to give an account in so much detail of electro-optics, including the electromagnetic theory of light, and of dynamo-electric machinery.

The final chapter, Elektrochemie, Electrolyse, contains a fair discussion of the motion of ions, of electrolytic dissociation, winding up with a sketch of the energy theory of the voltaic cell.

The final part of the second volume deals with heat, and here again, in 130 pages, the author effects quite a marvel of condensation. Temperature, expansion, the air thermometer, all are soundly and clearly treated, and there is an absence of the terrible confusion about scales of the mercury and air thermometers which is so common. For example, we came across again the other day the statement that air is an excellent thermometric substance because its expansion is so uniform. The same thing is generally claimed in the same books for mercury, and the authors never seem to think that this uniformity is not absolute, but must be relative to some standard. They do not perceive that the standard they set up is really the expansion of the mercury itself in

the thermometer. Here, however, there is no such nonsense.

The third book of this part deals with thermodynamics, and we must enter our protest once more against the mode of treatment adopted for absolute temperature. As is usual in German and French treatises temperature is first defined by the so-called law of gases, and then based on the hypothetical something called a perfect gas. Then that notion of temperature is carried into the discussion of the indicator diagrams given by Carnot's engine. Of course if a perfect gas is properly and clearly defined the discussion *can* be made logically consistent, though in what seems a forced and unnatural way; and Prof. Riecke is careful to state, though not quite all at one place, what the properties of his perfect gas are.

The true method is to define absolute temperature by means of a perfect engine, so as to get a scale independent of the properties of any known substance, and then Joule and Thomson's experiment becomes a comparison of the scales of different gas thermometers with the absolute scale, that is a test of the perfection of the gases. So far as we have been able to see, the name of Thomson is not mentioned in this section of the work!

In taking leave of this treatise we wish to say that students owe much to Prof. Riecke for giving them a readable, not too abstruse, and yet thoroughly sound and fairly full discussion of the elements of physics. To many German students who have not time to struggle through the larger treatises this book must be very welcome.

A GRAY

A NEW DEPARTURE BY THE RAY SOCIETY

The Tailless Batrachians of Europe Part II By G. A. Boulenger, FRS (London The Ray Society, 1898.)

WE recently reviewed under the above heading the first part of the above-mentioned work, which will become classical among popular treatises upon zoology, and the second part, following so close upon it, calls for nought but the highest admiration. In the 131 pages which compose its body, the Bufonidae, Hylidae, and Ranidae, are treated in a manner uniform with the contents of the first volume, with which it is serially pagged. There are 14 plates, of which 10 are coloured, 4 maps, and 44 text illustrations, all of the same excellence as in the first part, and the whole work well-nigh challenges criticism, it being praise sufficient to remark that it is its author's. Although the pages deal professedly with European animals, their value is materially enhanced by the recognition of the world-wide distribution of these, with especial reference to local varieties—as, for example, the Japanese and Chinese Bufones. The difficult topic of the racial varieties of the Ranidae is for the first time handled in popular terms, the author giving the results of his ripe experience in a concise tabular form which will be of the greatest use to both the way-side and professed naturalist. Nor is the experimental aspect of the study neglected, and concerning this, in his disproof of the Fischer-Sigwart hypothesis (p. 311),

the author once again displays a commendable enthusiasm and love of science for its own sake which cannot fail to exercise the healthiest influence upon the reader's mind. Equally encouraging is his frequent allusion to the work of the dilettanti, not a few among his critical observations and records as to geographical distribution and breeding period being culled from the pages of journals and the publications of local Natural History Societies, which the too academic critic might be apt to ignore. Under this head the incorporation of observations like those of Mr. Norman Douglass is deserving especial comment, as furnishing encouragement to the mere lover of nature and those content to seek our familiar creatures in localities in which they are unknown, and as bringing to these persons a full assurance that their efforts do not pass unnoticed by the leading masters of their craft. To the popular mind, the record of a toad's attempt to swallow a viper, and of the edible frog's more regular habit of snake capture, will especially appeal, as an interesting fact concerning the balance of nature.

The book concludes with an appendix of 16 pages, a bibliographical index of 13 pages; and an alphabetical index to the two parts. The appendix embraces a list of the specimens preserved in our National Museum at South Kensington, and to peruse this is to realise that the work is a popular commentary upon a collection unparalleled by that of any other museum in the world—a glorious possession of the British race. With this at his command the author could not have achieved other than a great result, but still by no means the least conspicuous feature about it is the stamp of his own individuality and personal influence which it bears. His book is worthy this unique material, and the best endeavours of all concerned in its accumulation; and while congratulating the Ray Society upon the success of their new departure, we earnestly hope that its executive will forthwith consider the advisability of making corresponding and ample provision for a companion work on the Batrachia Caudata, regarding that as at present the object most deserving their support, and most worthy their old-established reputation as pioneers in the popularisation of biology.

There are a few trivial matters of terminology in the present volume, such as the usage of the words "hand," "sternum," and "anus," and one or two expressions of orientation, to which exception might be taken, but these are altogether trivial where all else has been so nobly done.

OUR BOOK SHELF.

Morality independent of Obligation or Sanction. By M. Guyau. Translated from the French (second edition) by Gertrude Kapteyn. Pp. xii + 215 (London Watts and Co., 1898).

In the twilight of gods and systems has naturalism any word as to the conduct of life? The author of "The Irrigation of the Future" feels that the scientific spirit in its revolt can rest in no optimism theological or teleological, while, discounting pessimism of temperament as simply the symptom of unfitness of life, the pessimism put forward as a general solution can be shown to be bound up with psychological illusion and is negatived by

the will to live. If the systems afford us no certitude, and we cannot accept the anodyne of faith, what shall a spirit which doubts all that it may, and finds its chief probabilities in the indifference of nature and the relativity of knowledge, maintain as to the problems of that life which still goes on? Is it possible, upon the positive basis of facts which we cannot doubt, to found "a small house at the foot of the Tower of Babel," leaving the latter to rear itself to heaven, if it can, and not knowing whether in the end the new structure may not need its shelter?

As the conception of duty crumbles before analysis, its equivalents are to be found in the impulse to maintain and expand life in its productive fecundity, and in life the unconscious forces are as little negligible as the conscious. I can, therefore I must, overflow creatively into and upon other life, and in the spending is my gain. The ideas of expanding action are in themselves forces tending to realisation. Such expansion is necessarily social and even self-sacrificing. The struggle for existence, if it takes a purely egoistic direction, as in the case of violence, results in outward limitation and inner loss of equilibrium, while, supposing it to take the risk and, what the plain man means by, the responsibility of speculation or action, it realises the actual ideal of the moment, the hope which has not despaired of the commonweal. Thus morality without obligation is the outcome of naturalism. The so-called sanctions of morality are in part illusory, and are never wholly sanctions. The physical and physiological have no regard to intention. Remorse is not necessarily in the direction of morality. Punishment is justified only from the point of view of social defence, defence being the reaction upon attack which alone of our instincts does not lose force under the solvent of conscious analysis. We cannot substitute sanctions for obligation. The practical conclusion is a gospel of work and social fecundity, the theoretical that we stand, as it were, on the deck of some great ship lost between sky and water, and left to make what port it can; rudder there never was. But here the practical intervenes again. We will risk our all on our hopes. The rudder is still to make. "This is a great task, and it is our task." H. W. B.

Th. Thoroddsen, Geschichte der Isländischen Geographie. Vorstellungen von Island und seines Natur, und Untersuchungen darüber in alter und neuer Zeit. Autorisierte Übersetzung von August Gebhardt. Vol. I, 1897, vol. II, 1898. Pp. xvi + 238, and xvi + 384. (Leipzig B. G. Teubner.)

THESE volumes deal with the intellectual and social history of Iceland from the earliest times to the middle of the eighteenth century, and are by no means restricted to the geographical conditions of the island. Dr. Thoroddsen wrote in Icelandic and designed his book for his own countrymen, who remain in many ways one of the most cultured, at any rate of the most reading, peoples of Europe. He has spent most of his life in the detailed study of the geology of Iceland, on which he has written many monographs of great value, and now he is publishing the results of researches in a different direction, which have involved much searching of the archives of Iceland and Copenhagen; a great part of the text being derived from MSS which have never before been printed.

The translator appears to have done his work with care and discrimination, but it must have been an unusually arduous task, as the old documents cited were in archaic Icelandic very difficult to render into modern German; and Dr. Gebhardt has endeavoured to preserve their flavour by imitating the contemporary German style and spelling when translating them.

The work is arranged chronologically, beginning with a

discussion of the first reference to Iceland in classical writings, and proceeding to the first colonisation by Irish monks, the second by Norse exiles, the Golden Age of Icelandic discovery which followed, and the subsequent development of the most learned literary society in Europe. The mediæval accounts of Iceland are then discussed, but here the foreign reader is at a disadvantage, as he does not occupy the standpoint of the Icelander for whom the book was written, and loses much of the humour of the various misrepresentations of fact. The story of the narrow escape which Iceland made from becoming an English colony in the fifteenth century, when it was the great fishing ground for Bristol and Scarborough smacks, and the manner in which German commercial interests triumphed, has special interest for English readers. An account of the renaissance in Icelandic literature after the Reformation completes the first volume. The second volume deals largely with superstitions and witchcraft in the sixteenth and seventeenth centuries; and gives details of the first native descriptions of the country and the first surveys of Iceland, as well as recounting the services of Icelanders to science in general. These were, however, of no very great moment, and by no means so interesting to read of as the highly developed system of magic and witchcraft for which Iceland was famous in the preceding century.

An island of any sort is a fascinating topic to explore and to describe. It presents possibilities of completeness denied to countries which form part of a continent, and Dr. Thoroddsen has given his countrymen a book to study and to think over. For the sake of the foreign reader we hope that on the completion of the work he will himself retell the story in one handy volume, written with the object of making outsiders acquainted with Iceland and its people. H. R. M.

The Telephone. Outlines of the Development of Transmitters and Receivers. By Prof. William J. Hopkins. Pp. ix + 83. (New York and London. Longmans, Green, and Co., 1898.)

A CLEAR and connected explanation of the principles underlying the action and the design of telephone transmitters and receivers is given by Prof. Hopkins in this volume. The work is by no means exhaustive; indeed, men engaged in practical telephone construction may object that it is not full enough to be of real service. But as a general survey, for the instruction of students of telephony, the book contains a distinct view of the subject, into which details can be worked later on. The book begins with a chapter on the analysis of vibrations of sounding bodies. Following this is a short account of Reis's and Bell's telephones, and then come chapters on the development of transmitters, early successful types of transmitter, the results of systematic investigations upon transmitters of various types, granular transmitters, magneto instruments, and the design of receivers. This outline is sufficient to show that the volume provides students of practical electricity with a good view of telephone construction. The text is elementary enough to be read with interest by the general public.

Mathematical Examination Papers for Use in Navy Classes in Schools. By the Rev. J. L. Robinson, M.A. Pp. vii + 143. (London. Rivingtons, 1898.)

THIS collection of examination questions in arithmetic, algebra, geometry, mixed mathematics (including elementary trigonometry), and mechanics, and geometrical riders, will be found of real service by teachers preparing candidates for admission to naval cadetships of the Royal Navy. The student who works through the questions will be able to sit for the examination with an easy mind.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

The Aurora Borealis of September 9

I HAVE read, with much interest, in NATURE of September 15, the article concerning the aurora borealis of September 9, and it may be of interest to your readers to know that this

but very bright streamers in all directions, especially to the east. This latter formation was surrounded by quite black spaces of sky, which made the luminous phenomena look more beautiful.

Meanwhile, in the northern part of the sky, the aurora took the shape of ever-changing columns, and long, sometimes spiral and undulating bands, which twice, in the north-west and in the north-east, doubled, resembling curtains hanging one over the other.

A little after eleven I saw in the north a very strange formation of aurora, three vertical columns in their upper part were crossed by a bright horizontal streamer, extending nearly from north-west to north-east.

Soon after 11.30 the aurora began to vanish everywhere, and, in a very marked manner, took more and more the aspect of some luminous shapeless cloud. After 12 o'clock all traces of columns and streamers disappeared, and at 1 o'clock nothing more of the phenomenon was to be seen.

Fourier's Series

IN a letter to NATURE of October 6, Prof. Michelson, referring to the statement that a Fourier's series can represent a discontinuous function, describes "the idea that a real discontinuity can replace a sum of continuous curves" as "utterly at variance with the physicists' notions of quantity." If, as this seems to imply, there are physicists who hold "notions of quantity" opposed to the mathematical result that the sum of an infinite series of continuous functions may itself be discontinuous, they would be likely to profit by reading some standard treatise dealing with the theory of infinite series, such, for example, as Holston's "Trigonometry," and the paper by Sir G. Stokes quoted on p. 251 of that work.

Prof. Michelson takes a particular case. He appears to find a difficulty in the result that the sum of the series

$$y = \frac{1}{2} \sin x - \frac{1}{3} \sin 2x + \frac{1}{5} \sin 3x - \dots$$

is equal to x when x lies between $-\pi$ and π , is equal to $-\pi + x$ when x lies between π and 3π , and so on, and further is equal to zero when x is $-\pi$, or π , or 3π , and so on.

beautiful phenomenon displayed its splendours the same evening in all parts of Finland territory.

On that day I had the good fortune to see it in Helsingfors, from its earliest beginning to its end, in a clear, perfectly cloudless sky, and a calm and transparent air. These favourable conditions enabled me to sketch the principal movements of it, and I send you herewith a copy of the drawing I made.

The aurora was not only one of the most splendid that has been seen, but also that has appeared in our latitude for a long series of years. It began a little before 9 o'clock, and at 10 arrived at its maximum brilliancy, a state in which it, ever changing, remained till 11 o'clock, displaying the whole time an exceedingly beautiful brightness in all its parts.

The display began with a very bright arc in the north, but this very soon disappeared, while at the same moment exceedingly brilliant streamers extended at once up from the western and eastern horizons, sending immense columns to the zenith, and taking the shape of a colossal arc arching the whole sky from horizon to horizon. Masses of light flowed from both sides to the zenith, where they seemed to disappear. At 10 o'clock the great arc was interrupted on both sides by a dark region, the bright streamers remaining only on opposite horizons; but in the same moment a corona of the highest splendour appeared in the zenith, consisting of three nearly parallel streamers, stretching from west to east, and ending towards the west in the dark space, and towards the east in a beautiful fan of light. Half an hour later the corona took the shape of an immense dome, the ribs and columns of which stood around all parts of the horizon. The whole visible sky at that moment presented one single enormous dome of indescribable beauty. The brightest columns of this dome were to the west and to the east, those to the north were much less bright, and the columns to the south were scarcely visible. From every part of this dome streamers of light, without interruption, flowed up to the zenith.

At 11 o'clock, when the dome suddenly disappeared, the corona took the shape of a luminous spiral-ring, sending short

With the view of stating his difficulty simply, he has tried to sum this series, and the series obtained from it by differentiating its terms, for values of x of the form $\pi + \epsilon$, where it appears to be meant that ϵ is positive and less than 2π .

The series (thus obtained) for y and dy/dx are given by the equations

$$y = \sin \epsilon + \frac{1}{3} \sin 2\epsilon + \frac{1}{5} \sin 3\epsilon + \dots + \frac{1}{n} \sin n\epsilon + \dots$$

$$- \frac{1}{3} \frac{dy}{dx} = \cos \epsilon + \cos 2\epsilon + \cos 3\epsilon + \dots + \cos n\epsilon + \dots$$

Of the first series Prof. Michelson says: "This series increases with n until $n = \pi$. Suppose therefore $n = k\pi/m$, where k is a small fraction. The series will now be nearly equal to $m = k\pi$, a finite quantity even if $n = \infty$.

"Hence the value of y in the immediate vicinity of $x = \pi$ is not an isolated point $x = 0$, but a straight line $-y = mx$."

Of the second series he says that it "is nearly equal to n for values of n less than $k\pi$."

Neither of these statements is correct. The sum of the first series can be proved to be $\frac{1}{2}(\pi - \epsilon)$ when ϵ lies between 0 and 2π , and $-\frac{1}{2}(\pi + \epsilon)$ when ϵ lies between 0 and -2π , and it is zero when $\epsilon = 0$. The sum of n terms of the second series does not approach to any definite limit, as n is increased indefinitely; nor does the difference between the sum of this second series to n terms and the number n tend to zero or any finite limit, but the ratio of the sum to n terms and the number n tends to the definite limit zero as n is increased indefinitely.

The processes employed are invalid. It is not the case that the sum of an infinite series is the same as the sum of its first n terms, however great n is taken. It is not legitimate to sum an infinite series by stopping at some convenient n th term. It is not legitimate to evaluate an expression for a particular value of x , e.g. $x = \pi$, by putting $x = \pi + \epsilon$ and passing to a limit, to do so is to assume that the expression represents a continuous function. It is not legitimate to equate the differential coefficient of the sum of an infinite series to the sum of the differential coefficients of its terms; in particular the series given as representing dy/dx in the example is not convergent.

Lastly, Prof. Michelson says "it is difficult to see the meaning of the tangent if y were an isolated point." The tangent, at a point, to a curve, representing a function, has of course no meaning, unless the function has a differential coefficient, for the value corresponding to the point, and a function which has a differential coefficient, for any value of a variable, is continuous in the neighbourhood of that value.

Helium in the Atmosphere

THE letter of Mr. Baly in your issue of last week, corroborating the statement of Friedländer and Kayser that helium is a constituent of the atmosphere, induces me to put on record a further confirmation of the accuracy of this observation. Having had the opportunity, on June 20 last, of examining samples of the more volatile portions from liquid air, which had been handed to me by Prof. Dewar, I had no difficulty in seeing the lines of helium in them. Further, a sample of the helium separated by Prof. Dewar from bath gas (following the discovery of Lord Rayleigh) undoubtedly contained the substance called neon.

In giving these facts I am only confirming the observations of Prof. Dewar given to me in letters accompanying the samples of gas.

Triplet Lightning Flash.

At the suggestion of Lord Kelvin, I send you the enclosed photograph of a triplet lightning flash which was taken during a recent thunderstorm at Whitby, and under the following conditions.

The flash must have been about two miles distant (out at sea). The focus of the camera lens was 8 inches; the aperture, $f/64$; the plate, Ilford Empress. The camera was not stationary, but was purposely oscillated by hand. It was intended that its axis should describe a circular cone, but from the photograph the path appears to have been rather elliptical. Each revolution occupied about $1/80$ minute. From these rough data I estimate that the three flashes followed each other with a frequency of about 30 to 35 per second. They are identical in shape, but the top part of the lowest (left-hand) one is missing, and the bottom is screened. On the negative the centre flash is rather weaker than the other two. Each flash is sharply defined on the left edge and somewhat hazy on the right edge, due probably to the gradual cooling of the glowing gases, and showing that the lowest (left-hand) flash is the first of the three. The photograph also contains a faint image of a single flash. During this thunderstorm two other plates were exposed under the same conditions as the above, but no images were found on them.

Possibly the lightning was too far off, and the aperture too small.

In view of the importance of obtaining more definite information about lightning, I would suggest that in the presence of a thunderstorm photographs similar to the above should be taken. Greater accuracy than was possible under the above conditions could be attained by rigging up the following simple contrivance. An ordinary bedroom looking glass should be placed on a table in front of an open window facing the storm. The mirror should be inclined at any angle of 45° . The camera tripod, with its legs spread as wide apart as possible, should be placed on the table so that its centre is over the looking-glass. The camera, with its objective downwards, should be suspended from this centre by means of three strings, and should be made to swing in a circle by a gentle finger pressure close to the point of suspension. The period of revolution should be noted. Should any multiple flash imprint itself on the negative, it will now be possible to accurately measure the intervals of time, except

under the following conditions. If there are only two flashes, the radius of the circle described by the camera can only be guessed at. If the camera has described an ellipse, at least four lightning images are required to find its elements. A camera revolving on an axis passing through the objective would in some respects be more convenient to work with, but unless it is revolved by clock-work the time measurements would not be trustworthy. The aperture used by me, $f/64$, is probably too small except for very brilliant flashes, but if it is intended to allow several discharges to imprint themselves on one negative, a very large aperture will be found inconvenient because of the illumination of the landscape. The size of the aperture, rapidity of plate, and distance of each lightning flash should be noted to assist at forming some idea as to the heat generated.

The Centipede-Whale.

THE "Scolopendron Millipede," which forms the subject for the epigrams of Theodoridas and Antipater, and to which Mr. W. F. Sinclair kindly called my attention (NATURE, vol. lvi. p. 470), seems to mean a being quite different from the "Centipede-Whale" which Elian and Kaibara describe (see my letter, *ibid.*, p. 445), for the former apparently points to a huge skeleton of some marine animal, while the latter is an erroneous but vivid portrait of an animal actively swimming with numerous fins.

Major R. G. Macgregor, in his translation of the Greek Anthology (1864, p. 265), remarks upon the "Scolopendron Millipede" that the "word *millipeda* must be understood rather in reference to the extreme length of the monster than to the number of its feet." However, it would appear more likely that, in this similitude of the animal remains to the Myriapod, the numerous articulations of the vertebral column as well as its length played a principal part, should we take for comparison the following description of an analogous case from a Chinese work (Li Shih, "Shih-poh-wuh chi," written thirteenth century, [ap. ed., 1683, tom. x. fol. 6, 8])—"Li Men, a high officer (ninth century), during his stay in Pien-Chau, came in possession of one joint of a monstrous bone, capable of the use as ink-

stone (Yaw). A foreign tradesman who brought it from the South Sea stated it to be the vertebra of a centipede." Seeing that its use here alluded to is nowadays often repeated, we do not hesitate to conclude that this "vertebra of a centipede" was nothing other than the vertebra of a whale. A long series of the cetacean vertebrae, especially when it is separate from the skull yet remaining adhered with the fragments of the ribs, would, to the imagination of those crude folk, naturally furnish a ready sketch of a gigantic, marine centipede.

The "Centipede-Whale" of *Elisan* and *Kabara*'s descriptions are very probably certain species of sharks with the habit of swimming one following another. The reason is that while the fantastic figure of a six-legged sea serpent, that was cut up on the Orkney in 1808 and subsequently proved to be the shark *Scalioch maximus* (Ménager of the Wernerian Nat. Hist. Soc., Edin., vol. i, Plate XI, 1811), forcibly reminds us of the "Centipede-Whale," pictured in Gener's "Historia Animalium" (see my letter, *l.c.*) and in a Japanese work (Ilfruzumi, "Morokoshi Kimmōdzu," 1719, tom xiv fol 6, a), *Tanigawa Shisei*, the Japanese glossarist (1707-1776), mentions in his "Wakun-no-Shiori" (ed. 1887, 3rd ser., tom xvi, fol 8, a) the "Centipede Shark" (*Mukadebune*), which is doubtless identical with the centipede whale. That the manner of the natiators' movements of some sharks—to which are attributable the words of *Elisan*, "idque confertur posse cum trimetris laetis magnitudinis, atque per multos pedibus utrumque ordine sitis, tanquam ex scalmis appendis, natant"—should suggest to the mind the exact representation of a terrestrial centipede, is well evinced by the Japanese word *Mukadebune* (= Centipede-Boat), signifying a slender boat with many oars in pairs that have to be moved like the legs of a running centipede (mentioned in Yuasa, "Jōzan Kidan," 1739, tom xv fol 12, a).

An older description of such a fabulous creature in the Far East, occurs in the Chinese "History of the Su Dynasty" (written seventh century A.D.), and reads thus: "Chin-Lah (Cambodia) produces a fish named *Fu Hu*, which resembles Mud Eel (*Monopterus javanensis*, Lacépède, according to Molendoff), but with the bill shaped like the parrot's, and has eight legs."

When we set apart the more or less allied stories of the Dragon (Chinese, *Lung*, and Japanese, *Tatsu*), which very probably originates in the phenomena of waterspout and whirlpool,¹ we hardly know from the Far Eastern sources anything like the Sea-Serpent stories so much in circulation in the West. In the Far East, indeed, the Sea-Serpent seems to have totally given place to the Sea Centipede, both having the identical, diverse origins—the back-bone of a whale, the sharks, and some Cephalopods (*cf.* "Encyc. Brit.", ninth ed., vol. xxi, pp. 608-610, and my letter, *l.c.*). Thus, in China, there prevails a long-established belief in the existence of huge centipedes in the South Sea, very valuable for their flesh and skin, the former tasting like prawn and much superior to beef, and the latter being useful for making drum.²

Turning to Japan, we read in the "Konjaku Monogatari" (written by Minamoto-no-Takakuni in the eleventh century, ed. Izawa, tom xv fol 2-7), a narrative of the seven anglers, who killed a centipede about 10 feet long, that came from amidst a wide sea to combat with a huge serpent, the master of an island. This story of the "Sea Centipede" is perhaps a prototype of the later but far more popularised legend of Tawara Toda's slaughter of a monstrous Myrskop, which, the tradition says, used to molest a dragon in Lake Biwa.³

KUMAGOSU MINAKATA

7 Effie Road, Waltham Green, September 17.

¹ For similar misconceptions current among the Arabs, vide "Encyc. Brit.", *l.c.*, p. 610.

² The first description of such a gigantic centipede occurs in a poem by Koh Hing (written c. 1500). In the poem a centipede was found drowned by sea side on a coast of Kwang-Chau, and a man was fortunate enough to secure 500 *li* weight of edible flesh by opening its "claws." "Yuen kien lui ha," 1797, tom. cxxxv, fol 12, a, k. Here, too, said "claw" would seem no other than the shark's fin, which in recent times has become the article of commercial importance with the Chinese. Even in the Imperial Geography ("Ta-Tung-tung-shih," tom. cxxxv, fol. 19, a), compiled so lately as the eighteenth century, a similar centipede is described as native to Anam, which *Tanigawa* (*l.c.*) happily identifies with his "Centipede-Shark."

³ The latter story is first recorded in "Taleiki" (written fourteenth century, lib. xv, ch. 3), although its hero flourished in the tenth century (for its brief account see Mr. E. Gilbert's article in the *Times* and *Proc. Soc. Sci. London*, 1897, vol. p. 112). *Shichida-no-Kura* (1810, ch. v), gives an abridged account of this tradition, but does not refer to the "Sea-Centipede" story quoted above.

The Moon's Course.

THE moon's unique course was not known, in J. Ferguson's time, to be so peculiar as it now appears; for only five other satellites were then known, but now we know twenty, and still no other that has a path always concave to the sun.

It arises, of course, from her being more pulled by the sun than by the earth. All the others are more pulled by their primaries than by the sun. The distance from our earth where she balances the sun is but 1/560th of the sun's. But the moon's mean distance is fully a 386th of the sun's. The distance from Jupiter where he balances the sun is a 33rd of his own. That from Saturn is over a 60th of his own distance. That from Uranus a 155th; from Neptune a 140th; but from Mars only a 1760th; and in every case their furthest satellites are much nearer. Our moon's form of path is quite unique in the universe, so far as known.

A Simple Method of Making Light Mirrors.

THE following description of a simple and inexpensive method of making optically perfect mirrors for galvanometers and similar instruments will, I think, be of interest to many of your readers.

Strips of French plate-glass, about 5 mm (thick and 20 mm long, are well silvered and carefully polished with rouge. The silvered strip is placed upon glass on a flat stone or other firm support, and a light blow is struck with the edge of a hammer a little distance back from the silvered face. If the blow is well directed, a chip of glass of circular or elliptical form will be broken out. The nearer the edge the blow is struck the thinner the mirror will be. Of course not every blow will produce a good mirror, but with a little practice a strip 10 centimetres long should yield a dozen good mirrors, of assorted weights and sizes, which may be cemented to a card and put away in a box for use as occasion requires. Since the silver surface is exposed, it will tarnish in time; but as the expense and trouble involved in making the mirrors is so slight, and the definition given by them when new is so perfect, one can afford to renew them once a year if necessary. The method of silvering mirrors given in the "Encyclopædia Britannica" gives a surface well adapted to this purpose.

Animals and Poisonous Plants.

WHEN visiting lately the herbaraceous department in the Royal Botanic Gardens, Regent's Park, I noticed that nearly all the berries had disappeared from the deadly nightshade, *Atropa belladonna*, the calyx being left untouched. The foreman of the herbaraceous department told me that he believed they had been eaten by blackbirds, which are very active in the bushes; also that the seeds of *Datura stramonium* are eagerly devoured by mice. Can any of your readers confirm this statement of animals feeding on poisonous plants? In *Natura Naturæ* for October, I notice a statement of a report that wild rabbits feed on the leaves of the belladonna.

ALFRED W. BENNETT.

Crannogs in Estuaries.

REFERRING to the notices on this subject in *NATURE* of September 15 and 29, I beg to say that, in 1879, I discovered a crannoge constructed on a bed of peat, below high-water mark, in Ardmore Bay, Co. Waterford. It was at the mouth of a small stream.

The diameter of the enclosure was about 100 feet. It was surrounded by a double fence of massive piles, apparently sharpened with the stone axe. The interior contained matted beams and cleft panels of the dwelling, and portions of the walled partitions, traces of which covered the enclosed area in the form of pointed staves whose ends remained in the peat.

The kitchen midden contained bones of horse, ox, goat, pig, and red deer, the usual bill of fare found in the ruins of the country.

A paper on this crannoge was published in the *Proceedings of the Royal Irish Academy*, December 1880, and the site has been visited by Prof. Boyd Dawkins. It is covered by every tide, and the crannoge is now almost obliterated.

Cappagh, Fermoy, October 1.

R. J. USSHER

A SHORT HISTORY OF SCIENTIFIC INSTRUCTION.¹

I.

THE two addresses by my colleagues Profs. Judd and Roberts-Austen have drawn attention to the general history of our College and the details of one part of our organisation. I propose to deal with another part, the consideration of which is of very great importance at the present time, for we are in one of those educational movements which spring up from time to time and mould the progress of civilisation. The question of a Teaching University in the largest city in the world, Secondary Education, and so-called Technical Education are now occupying men's minds.

At the beginning it is imperative that I should call your attention to the fact that the stern necessities of the human race have been the origin of all branches of science and learning; that all so-called educational movements have been based upon the actual requirements of the time. There has never been an educational movement for learning's sake, but of course there have always been studies and students apart from any of those general movements to which I am calling attention, still we have to come down to the times of Louis Quatorze before the study of the useless, the *mine inutile*, was recognised as a matter of national concern.

It is perhaps the more necessary to insist upon stern necessity as being the origin of learning, because it is so difficult for us now to put ourselves in the place of those early representatives of our race that had to face the problems of life among conditionings of which they were profoundly ignorant when night meant death; when there was no certainty that the sun would rise on the morrow, when the growth of a plant from seed was unrecognised, when a yearly return of seasons might as well be a miracle as a proof of a settled order of phenomena, when, finally, neither cause nor effect had been traced in the operations of nature.

It is doubtless in consequence of this difficulty that some of the early races have been credited by some authors with a special love of abstract science, of science for its own sake, so that this, and not stern necessity, was the motive of their inquiries. Thus we have been told that the Chaldeans differed from the other early races in having a predilection for astronomy, another determining factor being that the vast plains in that country provided them with a perfect horizon.

The first historic glimpses of the study of astronomy we find among the peoples occupying the Nile Valley and Chaldea, say 6000 B.C.

But this study had to do with the fixing of the length of the year, and the determination of those times in it in which the various agricultural operations had to be performed. These were related strictly to the rise of the Nile in one country and of the Euphrates in the other. All human activity was in fact tied up with the movements of the sun, moon and stars. These, then, became the gods of those early peoples, and the astronomers, the seers, were the first priests; revered by the people because as interpreters of the celestial powers they were the custodians of the knowledge which was the most necessary for the purposes of life.

Eudemus of Rhodes, one of the principal pupils of Aristotle, in his History of Geometry, attributes the origin of geometry to the Egyptians, "who were obliged to invent it in order to restore the landmarks which had been destroyed by the inundation of the Nile," and observes "that it is by no means strange that the invention of the Sciences should have originated in practical needs."² The new geometry was brought from Egypt to Greece by Thales three hundred years before Aristotle was born.

¹ An address delivered at the Royal College of Science by Sir Norman Lockyer, K.C.B., F.R.S., on October 6.

² "History of Geometry from Thales to Euclid," p. 2 (Allman)

When to astronomy and geometry we add the elements of medicine and surgery, which it is known were familiar to the ancient Egyptians, it will be conceded that we are, in those early times, face to face with the cultivation of the most useful branches of science.

Now, although the evidence is increasing day by day that Greek science was Egyptian in its origin, there is no doubt that its cultivation in Greece was more extended, and that it was largely developed there. One of the most useful and prolific writers on philosophy and science who has ever lived, Aristotle, was born in the fourth century B.C. From him, it may be said, dates a general conception of science based on observation as differing from experiment. If you wish to get an idea of the science of those times, read his writings on Physics and on the Classification of Animals. All sought in Aristotle the basis of knowledge, but they only read his philosophy, Dante calls him "the Master of those who know."³

Why was Aristotle so careful to treat science as well as philosophy, with which his master, Plato, had dealt almost exclusively?

The answer to this question is of great interest to our present subject. The late Lord Playfair⁴ in a pregnant passage, suggests the reason, and the later history of Europe shows, I think, that he is right.

"We find that just as early nations became rich and prosperous, so did philosophy arise among them, and it declined with the decadence of material prosperity. In those splendid days of Greece, when Plato, Aristotle, and Zeno were the representatives of great schools of thought, which still exercise their influence on mankind, Greece was a great manufacturing and mercantile community; Corinth was the seat of the manufacture of hardware, Athens that of jewellery, shipbuilding and pottery. The rich men of Greece and all its free citizens were actively engaged in trade and commerce. The learned class were the sons of those citizens, and were in possession of their accumulated experience derived through industry and foreign relations. Thales was an oil merchant, Aristotle inherited wealth from his father, who was a physician, but, spending it, is believed to have supported himself as a druggist till Philip appointed him tutor to Alexander. Plato's wealth was largely derived from commerce, and his master, Socrates, is said to have been a sculptor. Zeno, too, was a travelling merchant. Archimedes is perhaps an exception, for he is said to have been closely related to a prince; but if so, he is the only princely discoverer of science on record."

In ancient Greece we see the flood of the first great intellectual tide. Alas! it never touched the shores of Western Europe, but it undoubtedly reached to Rome, and there must have been very much more observational science taught in the Roman studia than we generally imagine, otherwise how account for Pliny, the vast public works, their civilising influence carried over sea and land from beyond Bah-el-Mandeb to Scotland? In some directions their applications of science are as yet unsurpassed.

With the fall of the Roman Empire both science and philosophy disappeared for a while. The first wave had come and gone; its last feeble ripples seem to have been represented at this time by the gradual change of the Roman secular studia wherever they existed into clerical schools, the more important of which were in time attached to the chief cathedrals and monasteries; and it is not difficult to understand why the secular (or scientific) instruction was gradually replaced by one more fitted for the training of priests.

It is not to be wondered at that the ceaseless strife in the centre of Europe had driven what little learning there was to the Western and Southern extremities where

³ "Inferno," c. iv. 130 et seq.

⁴ "Subjects of Social Welfare," p. 206

the turmoil was less—I refer to Britain and South Italy—while the exiled Nestorians carried Hellenic science and philosophy out of Europe altogether to Mesopotamia and Arabia.

The next wave, it was but a small one, had its origin in our own country. In the eighth century England was at its greatest height, relatively, in educational matters; chiefly owing to the labours of two men. Bede, generally called the Venerable Bede, the most eminent writer of his age, was born near Monkwearmouth in 673, and passed his life in the monastery there. He not only wrote the history of our island and nation, but treatises on the nature of things, astronomy, chronology, arithmetic, medicine, philosophy, grammar, rhetoric, poetry, music, basing his work on that of Pliny. He died in 735, in which year his great follower was born in Yorkshire. I refer to Alcuin. He was educated at the Cathedral School at York under Archbishop Egbert, and having imbibed everything he could learn from the writings of Bede and others, was soon recognised as one of the greatest scholars of the time. On returning from Rome, whither he had been sent by Eabald to receive the pallium, he met Karl the Great, King of the Franks and Lombards, who eventually induced him to take up his residence at his Court, to become his instructor in the sciences. Karl (or Charlemagne) then was the greatest figure in the world, and although as King of the Franks and Lombards, and subsequently Emperor of the Holy Roman Empire, his Court was generally at Aachen, he was constantly travelling throughout his dominions. He was induced, in consequence of Alcuin's influence, not only to have a school always about him on his journeys, but to establish, or foster, such schools wherever he went. Hence it has been affirmed that "France is indebted to Alcuin for all the polite learning it boasted of in that and the following ages." The Universities of Paris, Tours, Fulden, Soissons and others were not actually founded in his day, but the monastic and cathedral schools out of which they eventually sprung were strengthened, and indeed a considerable scheme of education for priests was established, that is, an education free from all sciences, and in which philosophy alone was considered.

Karl the Great died in 814, and after his death the eastward travelling wave, thus started by Bede and Alcuin, slightly but very gradually increased in height. Two centuries later, however, the conditions were changed. We find ourselves in presence of interference phenomena, for then there was a meeting with another wave travelling westwards, and this meeting was the origin of the European Universities. The wave now manifested travelling westerly, spread outward from Arab centres first and finally from Constantinople, when its vast stores of Greek lore were opened by the conquest of the city.

The first wavelet justified Eudemus' generalisation that "the invention of the Sciences originated in practical needs," and that knowledge for its own sake was not the determining factor. The year had been determined, stone circles erected almost everywhere, and fires signalled from them, giving notice of the longest and shortest days, so that agriculture was provided for, even away from churches and the Festivals of the Church. The original user of geometry was not required away from the valleys of the Nile, Tigris and Euphrates, and, therefore, it is now Medicine and Surgery that come to the front for the alleviation of human ills. In the eleventh century we find Salerno, soon to be famed throughout Europe as the great Medical School, forming itself into the first University. And Medicine did not exhaust all the science taught, for Adelard listened there to a lecture on "the nature of things," the cause of magnetic attraction being one of the "things" in question.

This teaching at Salerno preceded by many years the study of the law at Bologna and of theology at Paris.

The full flood came from the disturbance of the Arab wave-centre by the Crusades, about the beginning of the twelfth century. After the Pope had declared the "Holy War," William of Malmesbury tells us, "The most distant islands and savage countries were inspired with this ardent passion. The Welshman left his hunting, the Scotchman his fellowship with vermin, the Dane his drinking party, the Norwegian his raw fish." Report has it that in 1096 no less than six millions were in motion along many roads to Palestine. This, no doubt, is an exaggeration, but it reflects the excitement of the time, and prepares us for what happened when the Crusaders returned, as Green puts it, "the western nations, including our own, were quickened with a new life and throbbing with a new energy." . . . A new fervour of study sprang up in the West from its contact with the more cultured East. Travellers like Adelard, of Bath, brought back the first rudiments of physical and mathematical science from the schools of Cordova or Bagdad. The long mental inactivity of feudal Europe broke up like ice before a summer's sun. Wandering teachers, such as Lanfranc or Anselm, crossed sea and land to spread the new power of knowledge. The same spirit of restlessness, of inquiry, of impatience with the older traditions of mankind, either local or intellectual, that drove half Christendom to the tomb of its Lord, crowded the roads with thousands of young scholars hurrying to the chosen seats where teachers were gathered together."

Studium generale was the term first applied to a large educational centre where there was a guild of masters, and whither students flocked from all parts. At the beginning of the thirteenth century the three principal studia were Paris, Bologna and Salerno, where theology and arts, law and medicine, and medicine almost by itself, were taught respectively, these eventually developed into the first universities¹.

English scholars gathered in thousands at Paris round the chairs of William of Champeaux or Abelard, where they took their place as one of the "nations" of which the great Middle Age University of Paris was composed.

We have only to do with the Arts faculty of this University. We find that the subject-matter of the liberal education of the Middle Age there dealt with varied very little from that taught in the schools of ancient Rome.

The so-called "artians," students of the Arts faculty, which was the glory of the University and the one most numerously attended, studied the seven arts of the trivium and quadrivium—that is, grammar, rhetoric, dialectic and arithmetic, geometry, music, astronomy².

This at first looks well for scientific study, but the mathematics taught had much to do with magic, arithmetic dealt with epics, golden numbers, and the like. There was no algebra, and no mechanics. Astronomy dealt with the system of the seven heavens.

Science, indeed, was the last thing to be considered in the theological and legal studia, and it would appear that it was kept alive more in the medical schools than in the Arts faculties. Aristotle's writings on physics, biology, and astronomy were not known till about 1230, and then in the shape of Arab-Latin translations. Still it must not be forgotten that Dante learned some of his astronomy, at all events, at Paris.

Oxford was an offshoot of Paris, and therefore a theological studium, in all probability founded about 1167,³ and Cambridge came later.

Not till the Reformation (sixteenth century) do we see

¹ "History of the English People," i. 198.

² See "Histoire de l'Université de Paris," Cr  vier, 1791, *passim*.

³ Enumerated in the following Middle Age Latin verse:

"Lingua, tropus, ratio, numerus, tonus, angulus, astrum."

⁴ "Universities of Europe in the Middle Ages," Kaschall, vol. ii. p. 344.

any sign of a new educational wave, and then we find the two which have had the greatest influence upon the history of the world—one of them depending upon the Reformation itself, the other depending upon the birth of experimental inquiry.

Before the Reformation the Universities were priestly institutions, and derived their authority from the Pope. The Universities were for the few, the education of the people, except in the various crafts, was unprovided for.

The idea of a general education in secular subjects at the expense of the State or of communities is coeval with the Reformation. In Germany, even before the time of Luther, it was undreamt of, or rather, perhaps, one should say, the question was decided in the negative. In his day, however, his real first made itself heard in favour of education, as many are now making themselves heard in favour of a better education, and in 1524 he addressed a letter to the Councils of all the towns in Germany, begging them to vote money not merely for roads, dikes, guns, and the like, but for schoolmasters, so that all children might be taught; and he states his opinion that if it be the duty of a State to compel the able-bodied to carry arms, it is *à fortiori* its duty to compel its subjects to send their children to school, and to provide schools for those who without such aid would remain uneducated.

Here we have the germ of Germany's position at the present day, not only in scientific instruction but in everything which that instruction brings with it.

With the Reformation this idea spread to France. In 1560 we find the States General of Orleans suggesting to Francis II a "levée d'une contribution sur les bénéfices ecclésiastiques pour raisonnablement stipendier des pédagogues et gens lettrés, en toutes villes et villages, pour l'instruction de la pauvre jeunesse du plat pays, et soient tenus les pères et mères, à peine d'amende, à envoyer les dits enfants à l'école, et à ce faire sous contrainte par les seigneurs et les juges ordinaires."

Two years after this suggestion, however, the religious wars broke out; the material interests of the clerical party had predominated, the new spirit was crushed under the iron heel of priestcraft, and the French, in consequence, had to wait for three centuries and a revolution before they could get comparatively free.

In the Universities, or at all events alongside them, we find next the introduction, not so much yet of science, as we now know it, with its experimental side, as of the scientific spirit.

The history of the Collège de France, founded in 1531 by Francis the First, is of extreme interest. In the fifteenth century, the studies were chiefly literary, and except in the case of a few minds they were confined merely to scholastic subtilties, taught (I have it on the authority of the Statistique de l'Enseignement Supérieur) in barbarous Latin. This was the result of the teaching of the faculties, but even then, outside the faculties, which were immutable, a small number of distinguished men still occupied themselves in a less rigid way in investigation, but still these studies were chiefly literary. Among those men may be mentioned Danes, Postel, Dole, Guillaume Budé, Lefèvre d'Étaples, and others, who edited with notes and commentaries Greek and Latin authors whom the Universities scarcely knew by name. Hence the renaissance of the sixteenth century, which gave birth to the Collège de France, the function of which, at the commencement, was to teach those things which were not in the ordinary curriculum of the faculties. It was called the *Collège des Deux Langues*, the languages being Hebrew and Greek. It then became the *Collège des Trois Langues*, when the king, notwithstanding the opposition of the University, created in 1534 a chair of Latin. There was another objection made by the University to the new creation: from the commencement the courses were free, and this feeling was not decreased by the fact that around the celebrated masters

of the Trois Langues a crowd of students was soon congregated.

The idea in the mind of Francis the First in creating this Royal College may be gathered from the following Edict, dated in 1545: "François, &c., savoir faisons à tous présents et à venir que Nous, considérant que le savoir des langues, qui est un des dons du Saint-Esprit, fait ouverture et donne le moyen de plus entière connaissance et plus parfaite intelligence de toutes bonnes, honnêtes, saines et salutaires sciences. . . . Avons fait faire pleinement entendre à ceux qui y voudraient vacquer, les trois langues principales, Hébraïque, Grecque, et Latine, et les *livres esquels les bonnes sciences* sont le mieux et le plus profondément traitées. A laquelle fin, et en suivant le décret du concile de Vienne, nous avons pièce ordonné et établi en notre bonne ville de Paris, un bon nombre de personnages de savoir excellent, qui lisent et enseignent publiquement et ordinairement les dites langues et sciences, maintenant florissant autant ou plus qu'elles ne firent de bien longtemps. . . . auxquels nous lecteurs avons donné honnêtes gages et salaires, et iceux fait pourvoir de plusieurs beaux bénéfices pour les entretenir et donner occasion de mieux et plus continuellement entendre au fait de leur charge. . . . &c."

The Statistique, which I am following in this account, thus sums up the founder's intention—"Le Collège Royal avait pour mission de propager les nouvelles connaissances, les nouvelles découvertes. Il n'enseignait pas la science faite, il la faisait."

It was on account of this, more than on account of anything else, that it found its greatest enemy in the University. The founding of this new College, and the great excitement its success occasioned in Paris, were, there can be little doubt, among the factors which induced Gresham to found his College in London in 1574.

These two institutions played a great part in their time. Gresham College, it is true, was subsequently strangled, but not before its influence had been such as to permit the Royal Society to rise phoenix-like from its ashes, for it is on record that the first step in the forming of this Society was taken after a lecture on astronomy by Sir Christopher Wren at the College. All connected with them felt in the time the stupendous change of thought in the century which saw the birth of Bacon, Galileo, Gilbert, Hervey, Tycho Brahe, Descartes and many others that might be named, and of these, it is well to remark, Gilbert, Hervey and Galileo were educated in medical schools abroad.

Bacon was not only the first to lay down *regula philosophandi*, but he insisted upon the far-reaching results of research, not forgetting to point out that "*lucifera experientia, non fructifera querenda*,"¹ as a caution to the investigator, though he had no doubt as to the revolution about to be brought about by the ultimate application of the results of physical inquiry.

As early as 1560 the Academia Secretorum Naturæ was founded at Naples, to be followed by the Lincei in 1609, the Royal Society in 1645, the Cimento in 1657, and the Paris Academy in 1666.

From that time the world may be said to have belonged to science, now no longer based merely on observation but on experiment. But, alas! how slowly has it percolated into our Universities.

The first organised endeavour to teach science in schools was naturally made in Germany (Prussia), where, in 1747 (nearly a century and a half ago), Realschulen were first started, they were taken over by the Government in 1832, and completely reorganised in 1859, this step being demanded by the growth of industry and the spread of the modern spirit. Eleven hours a week were given to natural science in these schools forty years ago.

Teaching the Teachers.

Until the year 1762 the Jesuits had the education of France almost entirely in their hands, and when, therefore, their expulsion was decreed in that year, it was only a necessary step to create an institution to teach the future teachers of France. Here, then, we had the *Ecole Normale* in theory; but it was a long time before this theory was carried into practice, and very probably it would never have been had not Roland d'Erceville made it his duty, for more than twenty years, by numerous publications, amongst which is especially to be mentioned his "Plan d'Education," printed in 1783, to point out, not merely the utility, but the absolute necessity for some institution of the kind. As generally happens in such cases, this exertion was not lost, for, in 1794, it was decreed that an *Ecole Normale* should be opened at Paris, "ou seront appelés de toutes les parties de la République, des citoyens déjà instruits dans les sciences utiles, pour apprendre, sous les professeurs les plus habiles dans tous les genres, l'art d'enseigner."

To follow these courses in the art of teaching, one potential schoolmaster was to be sent to Paris by every district containing 20,000 inhabitants 1400 or 1500 young men, therefore, arrived in Paris, and in 1795 the courses of the school were opened first of all in the amphitheatre of the Museum of Natural History. The professors were chosen from among the most celebrated men of France, the sciences being represented by Lagrange, Laplace, Haury, Monge, Daubenton, and Berthollet.

While there was this enormous progress abroad, represented especially by the teaching of science in Germany and the teaching of the teachers in France, things slumbered and slept in Britain. We had our coal and our iron, our material capital, and no one troubled about our mental capital—least of all the universities, which had become, according to Matthew Arnold (who was not likely to overstate matters), mere *hauts lycées*, and "had lost the very idea of a real university,"¹ and since our political leaders generally came from the universities little more was to be expected from them.

Many who have attempted to deal with the history of education have failed to give sufficient prominence to the tremendous difference there must necessarily have been in scientific requirements before and after the introduction of steam power.

It is to the discredit of our country that we, who gave the perfected steam engine, the iron ship, and the locomotive to the world, should have been the last to feel the next wave of intellectual progress.

All we did at the beginning of the century was to found mechanics' institutions. They knew better in Prussia, "a bleeding and lacerated mass,"² after Jena (1806), King Frederic William III. and his councillors, disciples of Kant, founded the University of Berlin, "to supply the loss of territory by intellectual effort." Among the universal poverty money was found for the Universities of Königsberg and Breslau, and Bonn was founded in 1818. As a result of this policy, carried on persistently and continuously by successive Ministers, aided by wise councillors, many of them the products of this policy, such a state of things was brought about that not many years ago M. Ferdinand Lot, one of the most distinguished educationists of France, accorded to Germany "a supremacy in Science comparable to the supremacy of England at sea."

But this position has not been obtained merely by founding new universities. To Germany we owe the perfecting of the methods of teaching Science.

I have shown that it was in Germany that we find

¹ "Schools and Universities on the Continent," p. 391.

² "University Education in England, France and Germany," Sir Rowland Blennerhassett, p. 25.

the first organised science teaching in schools. About the year 1825 that country made another tremendous stride. Liebig demonstrated that science teaching, to be of value, whether in the school or the university, must consist to a greater or less extent in practical work, and the more the better; that book work was next to useless.

Liebig, when appointed to Giessen, smarting still under the difficulties he had had in learning chemistry without proper appliances, induced the Darmstadt Government to build a chemical laboratory in which the students could receive a thorough practical training.

It will have been gathered from this reference to Liebig's system of teaching chemistry, that still another branch of applied science had been created, which has since had a stupendous effect upon industry, and while Liebig was working at Giessen, another important industry was being created in England. I refer to the electric telegraph and all its developments, foreshadowed by Galileo in his reference to the "sympathy of magnetic needles."

Not only then in chemistry, but in all branches of science which can be applied to the wants of man, the teaching must be practical—that is, the student must experiment and observe for himself, and he must himself seek new truths.

It was at last recognised that a student could no more learn Science effectively by seeing some one else perform an experiment than he could learn to draw effectively by seeing some one else make a sketch. Hence in the German Universities the Doctor's degree is based upon a research.

Liebig's was the *fons et origo* of all our laboratories—mechanical, metallurgical, chemical, physical, geological, astronomical, and biological. J. NORMAN LOCKYER.

(To be continued.)

OPENING OF THE THOMPSON-YATES LABORATORIES AT UNIVERSITY COLLEGE, LIVERPOOL

THE latest addition to the noble series of buildings now fast surrounding the old lunatic asylum in which University College, Liverpool, started work seventeen years ago is devoted to the Schools of Physiology and Pathology. The professorships in these subjects were endowed and equipped by the late Mr George Holt some years ago, and now suitable laboratories, on a magnificent scale, have been erected by the generosity of the Rev. S. A. Thompson-Yates at a cost of nearly 30,000*l*.

The building is of Liverpool grey brick and Ruabon terra-cotta in the renaissance Gothic style. It is L-shaped, one wing extending towards the north, where it joins the pathological museum of the old medical school building, and the other towards the east, the entrance being at the angle where the wings join. There are three floors and a basement. The two upper floors are occupied by physiology, under Prof. Sherrington, and the ground floor and basement by pathology, under Prof. Boyce. A large lecture theatre, the fine staircase and halls, and a few other apartments for the use of students are common to the two departments. Simplicity of plan has been the aim of the architects (Messrs. A. Waterhouse and Son), and there has been little or no expenditure of space in corridors and passages. As some of the rooms are to accommodate large numbers of workers, and so require to be lofty, while others are the private studies of individuals where a high ceiling would mean waste of space, a free use has been made of the expedient of mezzanines, by which the smaller rooms have been interpolated between the floors. The lecture theatre is very completely fitted for lantern illustration, including the projection microscope, the chromosome, the

animatograph, the episcopo and skiopticon, and also very perfect arrangements for the projection of the spectrum. The Physiological Department contains, in addition, large rooms for:—Chemical physiology with separate work-places for over fifty students, and fuller accommodation for about six research workers; physical physiology enabling a class of more than thirty to carry out exercises on muscle and nerve at one time, each student's place being provided with electric light, water, gas, electric wire for supply of current, induction coil, electric battery, recording drum driven by fixed pulleys from the shafting running above the table, electric keys, and heliostat apparatus, &c.; histology with accommodation for about eighty students, with adjoining preparation and store rooms; also smaller chemical rooms, professor's private and photographic rooms, room for experiments in electrophysiology, and a smaller theatre for the demonstration of experiments. The Pathological Department has large rooms for:—Morbid histology with work-places for sixty students; bacteriological work with suction and force pumps for filtering, a bacterial mill for pulverising bacteria, and a plentiful supply of steam at high pressure to conduct the various boiling operations. There are also rooms for chemical pathology, museum preparator's work, incubators at constant temperature, private experimental work, pathological diagnosis society, bacteriological work of the city, gas analysis, and the professors' private rooms. Briefly stated the special features of the pathological laboratories are the impervious opaline slabs covering the tops of the work-benches, and diminishing the risk of contamination and facilitating cleaning, the use of steam for boiling operations, a plentiful electric supply working the lamps and the numerous motors, and a specially high-pressure water supply, and lastly the refrigerator chamber. Throughout the Thompson-Yates laboratories are fitted up in the most complete and perfect manner, both for teaching and research; and the favourable opinions which have been so freely expressed by the distinguished scientific visitors during the opening and following days may be briefly summed up in the quotation from Prof. Michael Foster's happy and stimulating speech at the banquet, that "they (the laboratories) produced two physiological effects—they took one's breath away, and they made one's mouth water."

The invitation from the Council and Senate of University College to the opening function was accepted by a large number of distinguished men of science and representatives of universities and medical schools from all parts of the country, including Lord Lister and Lord Kelvin, Earl Spencer and the Earl of Derby, the Bishops of Ripon, Carlisle, Chester and Liverpool, Prof. Virchow, Sir S. Wilks (President of the College of Physicians), the Vice-Chancellor of Cambridge University, Prof. M. Foster and Prof. Burdon Sanderson, the Presidents of the Royal College of Physicians and Surgeons of Edinburgh, Sir W. Turner, Sir W. Gardner, Sir Douglas Galton, Sir A. Geikie, Sir J. Crichton Browne, Mr. R. B. Haldane, M.P., Mr. Justice Kennedy, Sir James Russell, Prof. Rutherford, Dr. Lauder Brunton, Captain Abney, Prof. Rucker, Prof. Poulton, Prof. Gotch, Prof. Kanhack, Sir R. Thorne Thorne, Prof. Schafer, and many others. These guests, for the most part in their academic robes, walked in procession with the civic authorities, the University and College staff, forming a ceremonial that for stateliness, brilliance, and interest has probably never been equalled before in Liverpool.

The scientific and medical guests arrived in Liverpool on Friday, and that day and Sunday were given up to private hospitality and informal meetings at the College and elsewhere; while Saturday, October 8, was the date of the University Degree ceremony and the formal opening of the new laboratories.

The University function was arranged to take place

in St. George's Hall; and there, in the presence of the Lord Mayor and Corporation, the staff, graduates and students of the University, the distinguished guests, and a large concourse of citizens of Liverpool, the honorary degree of Doctor of Science was conferred upon Lord Lister by Earl Spencer, the Chancellor of the Victoria University.

Lord Lister was presented for the degree by Dr. Richard Caton, Chairman of the Medical Faculty, and formerly Professor of Physiology in University College; and both the Chancellor and Dr. Caton in their speeches drew attention to Lister's immortal life-work in the antiseptic methods of surgery, and to the benefits conferred thereby upon humanity and the lower animals.

After Lord Lister had been admitted to the degree by the Chancellor, and had signed the roll of graduates, the Principal of University College (Mr. R. T. Glazebrook, F.R.S.) made a statement as to the history of the medical school and of the erection of the new laboratories by Mr. Thompson-Yates. The generous donor himself was unable to be present, but a letter from him was read expressing good wishes.

Lord Lister then delivered a short address, for which a vote of thanks was proposed by the Lord Mayor of Liverpool, and seconded (in the absence of Lord Derby) by Mr. W. Rathbone, Vice-President of the College.

Lord Lister pointed out in eloquently simple language the necessity for such laboratories in medical education, their importance both in teaching and research, and the benefits they were calculated to confer upon the College, upon Liverpool, and upon the neighbourhood. Lord Lister then, with a boldness and wisdom which compelled admiration, made a dignified statement as to the utility and humanity of experiments upon animals, which coming from such a man on such an occasion cannot but have a most beneficial effect. He concluded this part of his address with the sentence, "While I deeply respect the humane feelings of those who object to this class of inquiry, I assure them that, if they knew the truth, they would commend and not condemn them."

After the function in St. George's Hall, the company proceeded to University College, where the brief ceremony of declaring the laboratories open was performed by Lord Lister, after the presentation of a key in a silver casket had been made by the Chairman of the College Council. A similar key was retained for presentation to Mr. Thompson-Yates. Lord Lister and the large assembly of invited guests were then conducted in parties through the laboratories, other parts of the College were also visited. Tea and refreshments were served in the Victoria building; and, finally, the Lord Mayor's banquet at the Town Hall in the evening brought to a conclusion the formal proceedings of what stands out as the first great University function in Liverpool.

College functions have been frequent; noble buildings and new laboratories belonging to University College have been opened before, but now for the first time the professors and students appeared not merely as members of the College, but of the Victoria University. Liverpool is to be congratulated not only upon the splendid new laboratories, not only upon the impressive ceremonial of their inauguration, but also upon the fact that the first honorary degree conferred by her University, in the City, has been bestowed upon such a man as Lord Lister.

THE OPENING ADDRESSES AT THE MEDICAL SCHOOLS.

IN respect of an opening address there seems at the medical schools no fixed rule; in some cases the first year's student plunges *in medias res*, and the first word he receives from his teachers is actually work; in others a more or less philosophical discourse, often, it must be

admitted, more suited to the practitioner or advanced student, forms the prelude to a medical curriculum. The actual need for an opening address on medical education is really somewhat less than would be thought, since the "Student's Numbers" of the *Lancet* or *British Medical Journal* contain usually all that can possibly be said in the way of general advice to the student, and these every student or his parents read. This fact, doubtless well known to those giving the addresses, is perhaps one explanation of the varied subject-matter which October after October gets worked up and delivered as introductory addresses. What is in a name? Whether the introductory address benefits the first year's student or not, it at any rate forms an excuse for a batch of interesting dissertations, which have at this season of the year, when returning from holiday and bent on work, an effect both stimulating and refreshing. Stimulating, because from these addresses we get glimpses of the varied character and enormous extent of the undiscovered country, which lies open to the scientific explorer, refreshing, because we get a few tastes, as it were, of the fruit of the promised land.

The address of addresses this year was Prof. Virchow's, which was printed fully in these columns last week. The Mason College, Birmingham, was fortunate in having Prof. Michael Foster as lecturer. The subject chosen was the nature and function of a university. Prof. Foster has a high ideal of what a university ought to be, and, in view of the formation of a Midland University, indicated at Birmingham, what should be the aims of those entrusted with the foundation of this University. It is a relief to-day, when universities are rather apt to be regarded as examination-framing and degree-giving machines, to hear an eloquent voice raised which emphasises the value to the medical student of research and individual laboratory supervision, as being not only the best but in the long run the quickest way of teaching him the way to think, and thus attack the problems which the future practice of his profession will present to him.

Mr. Turner, in his inaugural address at St. George's Hospital, directed the attention of his audience to, perhaps, a less ideal, but nevertheless an important subject. Mr. Turner contends, as many have done before, that the profession of medicine is not rewarded proportionally to its merits. Distinctions are *ceteris paribus* conferred less readily on medical men than on members of the legal or clerical profession. Further, authors have done a wrong to the medical profession on many occasions by distorting in fiction and elsewhere its characteristics. This, no doubt, is very true; but one is thankful that it is fast disappearing. That those in authority are not, or rather were not entirely to blame for these grievances is also equally true. The emergence of medical practice from crude empiricism to its present-day condition, demanding on the part of the medical unit higher intellectual faculties, as opposed to mere memory, which bring in their train an increased appreciation of the aesthetic, will certainly remedy the social position of the rank and file of the profession. The effect of this is already seen in the increasing numbers of medical *litterateurs* of the type of Oliver Wendell Holmes, and medical authors Mr. Turner rightly not only indicated the disease, but suggested a remedy. While deprecating any attempt at organisation allied to trade unionism, he exhorted his hearers "to make by force their merit known," and cultivate amongst themselves an *esprit de corps* which would essentially overcome whatever obstacles it encountered.

A practical medical subject was the text of Dr. Caley's address at St. Mary's Hospital—prevention in medicine. Dr. Caley contended that to whatever extent the science of hygiene might develop, the actual prevention of disease will also depend upon the rank and file of the medical profession and the public. Some interesting

points were brought out in this address with regard to some of Dr. Sidney Martin's researches on the effect of organically polluted soil on the retention of vitality by the typhoid bacillus. In the case of virgin soil inoculated with the bacillus, no signs of vitality were found after fourteen, twenty, or twenty-three days, in the case of polluted soil, the bacillus was thriving at the end of seven months. Dr. Caley emphasised the importance to Great Britain as a colonising power of the prevention of malarial fevers, and noted with satisfaction that, thanks to the new army medical regulations, a better class of army medical officer will be forthcoming. The lecturer further considered the application of prevention to tuberculous disease, and in this connection referred to the results of the Royal Commission on Tuberculosis and the recent French Tuberculosis Congress.

An important point in Dr. Voelcker's address at the Middlesex was the caution which he gave to students as to how they spoke of medical matters in lay circles. This might have been extended, as there can be no doubt of the incalculable harm that may be done by a student or doctor who is not possessed of tact. The public as a rule lose no time or spares no pains in making the most of what has the material in it of a medical scandal. Inebriate students have before now doubtless unwittingly been sources of great mischief.

At the Royal Free Hospital, Dr. Walter Carr discoursed upon "Fashion in Medicine." Bleeding naturally found a place amongst the historic medical fashions, as also did the administration of calomel. Two present fashions in medicine were, according to Dr. Carr, the anti-toxine treatment and the treatment by animal extracts. At the close of the address he touched, appropriately to his audience, upon the future of the medical woman. He rightly urged the necessity of keeping up the standard of the medical woman, and gave a note of warning with regard to the possibility of the success, which had finally attended the movement, producing a less valuable individual.

The Pharmaceutical Society of Great Britain had the fortune to be addressed by Sir James Crichton Browne. Sir James pointed out that the examination of chemists and druggists ought to proceed on different lines to that of medical students in that the former were, as a rule, earning their livelihood by more or less manual service all the time they were in *status pupillari*. Sir James discussed the sale of poisons and the possibility of new legislation upon this subject in the immediate future. The average poisoner, according to the lecturer, takes but little advantage of the recent discoveries of science. In this connection he pointed out the popularity of arsenic, which was used by Wonderton in his attempt, in 1384, to poison Charles VI of France and the Dukes of Valois, Berry, Burgundy, and Bourbon. This drug was also the basis of the "manna" of St. Nicholas of Bari, and Toffana of Naples, which caused the deaths of 600 persons. In Sir James' experience no medical poisoner has ever used a drug outside Schedule A of the Poisons Act. From this circumstance the lecturer drew an interesting inference—viz that medical poisoners, so far from being intellectual villains, were as a rule dull and stupid to a degree, since much more deadly and much less easily detectable substances lay to their hand, if only they would take the trouble to find them and be original. They are, in fact, another instance of intellectual incapacity being associated with moral debasement. The lecturer then entered upon the subject of disease toxins and allied bodies, and pointed out how in all probability the poisoner of the future would avail himself of this class of poison. In conclusion, the effect of anti-toxines in the prevention of the sequelae of the infective diseases was pointed out; and basing his observations upon the dictum of Sir William Gull, that a patient took ten years to recover from an attack of

typhoid fever, Sir James emphasised the benefit which would accrue to mankind from the use of these remedies.

Dr. Robert Saunby delivered an opening address at the Medical School of University College, Cardiff, on modern universities. The lecturer deplored the condition of university education in England so far as concerns medicine, and pointed to what was done by the State in Germany and France. This theme has been often dwelt upon, and not without effect. England is now waking up to the value of technical education, of creating places where men can pursue those studies which are to form their stock-in-trade for life.

The address at the Yorkshire College, Leeds, was given by Dr. Cullingworth upon the importance of personal character in the profession of medicine. The author referred to an interesting article by Sir James Paget on the result of an inquiry of what became of 1000 of his pupils fifteen years after their entry at St. Bartholomew's. This showed that 9 per cent. died within twelve years of their commencing practice, and forty-one, or about 4.5 per cent., during their pupillage, fifty-six failed entirely, the remainder were successful in all degrees varying from distinguished success to very limited success. This, on the whole, is not a bad average, and if it was possible to the medical student of 1870, more is possible and probable to the medical student of to-day.

From the above brief extracts it will be seen with what varied advice and dissertations the recruits of the medical profession have been introduced to their life study. The practitioner and advanced student, rendered more cynical, perhaps, by contact with his fellows, will be inclined, and possibly not altogether wrongly, to recall the words of Mephistopheles to the would-be medical student in *Faust*, and abide by them —

The trade of medicine's easiest of all
'Tis but to study all things—everywhere
Nature and man—the great world and the small.
Then leave them at haphazard still to fare

F. W. TUNNICLIFFE.

SURGEON-MAJOR J. E. T. AITCHISON, M.D., C.I.E., F.R.S.

BOTANY has lost another of its devotees. Dr. Aitchison died at Kew on the 30th ult., at the age of sixty-three, after two or three years of bad health, consequent on a weak heart and other complications. He was a man of fine physique, and of a genial and happy disposition. The son of Major J. Aitchison, H.E.I.C.S., he was born in India in 1835. After successfully studying medicine and surgery at Edinburgh, he entered the Bengal medical service in 1858, and remained in it for thirty years. But it was as a botanical explorer and an investigator of the vegetable products of the various countries he visited that he was known in the scientific world. Enthusiastic, enterprising, and persevering in no ordinary degree, he succeeded in forming valuable botanical collections under difficulties that would have discouraged and prevented many men. Science is primarily indebted to him for collecting plants and their products and local information concerning them. In these investigations he was indefatigable; and he had a rich field for his labours in North-west India, Afghanistan, Baluchistan, Persia, and Russian Turkestan. He seems to have been led to botanical pursuits by the study of Indian drugs, as in tracing their origin he became familiar with vegetable organography, and acquired a love for plants which he retained to the last. Indeed, he settled at Kew in order to be able to continue his studies. His first contribution (1863) to botanical

literature was an enumeration of the plants of the Jhelum district of the Punjab, with notes on their products and distribution. It was in this paper that he published the only new species, I believe, that he ever described independently. For the many novelties he subsequently discovered he always called in professional aid, being too modest and too anxious for accuracy to attempt it alone.

Subsequently, in 1869, he published a catalogue of the plants of the Punjab and Sindh, which, however, was a good deal more than a catalogue. This was followed by a lengthy paper on the flora and vegetable products of Lahul, a "Handbook" on the trade products of Leh, and a number of smaller contributions to botanical literature. But his great harvest was made in Afghanistan and the surrounding countries. In the winter of 1878, he accompanied the troops under General (now Sir Frederick) Roberts into the Kuram Valley, and the following year was appointed botanist to the expedition. A collection of some 15,000 specimens of dried plants was made between Thal and Peshawar, at elevations of 2500 to 15,000 feet. A further collection was made in 1880 in the same country; and in 1884 he was appointed naturalist to the Afghan Delimitation Commission. This was even more fruitful than the previous expeditions, yielding about 800 species, represented by 10,000 specimens. But Dr. Aitchison not only collected specimens, he also collected a large amount of local information concerning them. These immense collections were worked out at Kew, and the results published in the *Journal and Transactions* of the Linnean Society. The papers are prefaced by admirable descriptions of the vegetation and local conditions of the districts traversed. Apart from the plants collected by William Griffith during the first Afghan war (1839-40), Kew possessed very little from this interesting region, hence Aitchison greatly enriched the herbarium and museum. In addition to the papers mentioned, he wrote a number of articles on the medicinal and other vegetable products of commercial value. I had almost forgotten to mention that he also collected zoological specimens.

Personally Dr. Aitchison was of a most amiable and kind-hearted disposition, and this, combined with his fine presence, tact and medical knowledge, enabled him to mix with the natives with impunity, and obtain information that others could not. One of the first things he did on arriving at a place was to treat the sick, and his reputation preceded him, so that he was often approached and besought for aid. In 1883 he was created a Companion of the Order of the Indian Empire, and in the same year he was elected a Fellow of the Royal Society of London. Unfortunately the last year of his life was saddened by the loss of his wife, to whom he had been deeply attached.

He was occupied during the last two years in preparing a *Flora India Deserta*, to include the plants of North-western India, Baluchistan, and Afghanistan, but his ailments prevented him from doing more than collect materials. It is not possible to find at once an equally qualified person to carry this idea into effect.

Though Aitchison was little in society during the last four or five years, there are many who will feel the loss of one who was such a cheerful companion and warm friend.

W. BOTTING HEMSLEY.

CONFERENCE ON THE INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE.

AT the Royal Society on Monday evening, the President and Council held a reception to meet the delegates attending the international conference upon an international catalogue of scientific literature. The conference began on Monday, and practically all

countries actively engaged in scientific work are represented. The following is a list of delegates appointed to attend the conference:—

Austria.—Prof. L. Boltzmann (Kaiserliche Akademie der Wissenschaften, Vienna); Prof. E. Weiss (Kaiserliche Akademie der Wissenschaften, Vienna).

Belgium.—Chevalier Descamps (President de l'Institut International de Bibliographie, Brussels); M. Paul Otlet (Secrétaire-General de l'Institut International de Bibliographie, Brussels); M. H. Lafontaine (Directeur de l'Institut International de Bibliographie, Brussels).

France.—Prof. G. Darboux (Membre de l'Institut de France); Dr. J. Deniker (Bibliothécaire du Muséum d'Histoire Naturelle); M. E. Mascart (Membre de l'Institut de France).

Germany.—Prof. Dr. Klein, Geheimer Regierungsrath (University of Göttingen).

Hungary.—Dr. August Heller (Librarian, Ungarische Akademie, Buda-Pesth); Dr. Theodore Duka (in London).

Japan.—Prof. Einosuke Yamaguchi (Imperial University of Kyoto).

Mexico.—Señor Don Francisco del Paso y Troncoso.

Netherlands.—Prof. D. J. Korteweg (Universiteit, Amsterdam).

Norway.—Dr. Jørgen Brunchorst (Secretary, Bergenske Museum).

Sweden.—Dr. E. W. Dahlgren (Librarian, Kongl. Svenska Vetenskaps Akademi, Stockholm).

Switzerland.—Dr. Jean Henri Graf (President, Commission de la Bibliothèque Nationale Suisse); Dr. Jean Bernoulli (Librarian, Commission de la Bibliothèque Nationale Suisse).

United Kingdom.—Representing the Government The Right Hon. Sir John E. Gorst, G.C., M.P., F.R.S. (Vice-President of the Committee of Council on Education); Representing the Royal Society of London Prof. Michael Foster, Sec.R.S.; Prof. Arthur W. Rucker, Sec.R.S.; Prof. H. E. Armstrong, F.R.S., Sir J. Norman Lockyer, K.C.B., F.R.S., Dr. Ludwig Mond, F.R.S.

United States.—Dr. Cyrus Adler (Librarian, Smithsonian Institution, Washington).

Cape Colony.—Roland Trimmen, Esq., F.R.S.

India.—Lieut.-General Sir R. Strachey, G.C.S.I., F.R.S.; Dr. W. T. Blanford, F.R.S.

Natal.—Sir Walter Peace, K.C.M.G. (Agent-General for Natal).

New Zealand.—The Hon. W. P. Reeves (Agent-General for New Zealand).

Queensland.—The Hon. Sir Horace Tozer, K.C.M.G. (Agent-General for Queensland).

On Tuesday evening the Royal Society gave a dinner to the delegates at the Hôtel Métropole. Lord Lister occupied the chair, and many Fellows of the Society were present, in addition to the foreign representatives of science. The *Times* gives the following report of the speeches at the dinner:—

Prof. Rucker, in proposing "Science in all Lands," said that science had become the most cosmopolitan of all the professions. In his own case he had this year taken part, more or less, in four international meetings; and he did not think there was any body of men or any other profession in which such cordial arrangements were made for the recognition of merit, foreign or otherwise, as the Royal Society. They had a regular organisation for recognising merit outside the geographical boundaries of the nation to which men belonged. They recognised great scientific triumphs as being triumphs, not for one nation, but for the world. Names like those of Pasteur, Helmholtz, and Maxwell were recognized as names of which the whole world was proud. Science was gradually forming a permanent international conference of scientific men, all communicating with each other by writings, if not by speech, and

they were drawn together not only by the bonds of intellectual sympathy but by scientific friendship.

Prof. Darboux, of the University of Paris, acknowledging the toast in French, said that the ideas to which Prof. Rucker had given expression would receive the unreserved adhesion of all those who cultivated science for its own sake. The most illustrious scientific men always retained some trace of their origin and of their race, as might be seen in the differences between the genius of a Descartes, a Newton, a Cuvier, a Darwin, or a Lagrange. German science was characterised by depth and power; French science by greater clearness and better method; while English science, though frequently beset with difficulties and dangers, had by a bold and timely policy rescued free inquiry from being overwhelmed. Whenever men of science met one another face to face, notwithstanding the differences that might separate them, they felt drawn to each other by the bonds of common interests. Every man of science recognised in another seeker after truth, wherever he might be met, a friend; and, though he did not cease to uphold the love for his Fatherland, he was proud to participate, as the delegates were participating now, in a work of peace, concord, and civilisation.

Prof. Weiss, director of the Imperial Observatory, Vienna, in proposing "Success to the Conference," said he had spent a few years in England in early childhood, and had learnt to love the English people; and in declining age he had occasion to admire the scientific men of England—their earnestness and the skilful perseverance with which they carried out their researches. He trusted that the conference would be a success, and that it would form the foundation of an international catalogue of scientific literature which would redound to the benefit of science and to the glory of England.

Sir John Gorst, in acknowledging the toast, said that the conference, as far as his experience had gone, seemed to be an admirable instrument for forwarding the scientific purpose for which it had assembled. In the first place, its wisdom was derived from every part of the world. Amid all this diversity of knowledge, surely it was reasonable to expect that some progress might be made in the work which the conference had in hand. According to the different way in which the question struck the peculiar idiosyncrasy of the different nationalities, they were much more likely to arrive at the truth than if left to blunder it out in their own British fashion without the assistance of minds very diverse from their own. He was not sure that the concert of Europe was in political affairs always a very brilliant success, but he thought that the concert of Europe in scientific affairs, free as it was from the drawbacks which accompanied political action—all the members of a conference of this kind being animated by only one desire, and that was the attainment of truth, having no personal and no national interest to serve outside the attainment of truth—a concert of that kind was one of the most valuable methods which the comity of modern nations had discovered for the propagation of all kinds of science and knowledge.

Prof. Korteweg proposed "The Royal Society." Lord Lister, in acknowledging the toast, said it had been a great satisfaction to hear from delegates the very cordial feelings expressed towards the society. He confessed that he had sometimes entertained fears that the task undertaken by the conference was too gigantic to be satisfactorily completed, but he felt encouraged that evening when he heard that the work seemed to be going forward satisfactorily, and that there was a fair prospect that it would be completed in such a way as would tend to cement even more firmly than at present the union of international science.

Prof. Armstrong proposed "Our Guests." Le Chevalier Descamps, delegate from the Belgian Government, expressed the gratitude which the delegates from foreign Governments felt at the kind reception accorded by the members of the Royal Society, and pointed out that their labours all tended in the direction of cementing still more closely the bonds of international scientific brotherhood. Their work in the conference, though being carried on modestly, was bound to be fruitful of good results, for bibliography had no pretensions to reform the world.

Prof. Klein proposed "The Secretaries," which was responded to by Prof. Michael Foster. Among the other speakers were Prof. Boltzmann, Sir Norman Lockyer, M. Mascart, Sir William Crookes, Dr. Graf, and Dr. Cyrus Adler.

NOTES.

WE understand that the vacancy in the Assistant-Directorship of Kew Gardens, caused by the appointment of Mr. D. Morris as Commissioner of Agriculture for the West Indies, will not be filled up. Mr. S. T. Dunn has been appointed Secretary to the Director.

THE *Botanischer Centralblatt* states that Prof. P. Knuth, of Kiel, is starting this month on a scientific expedition round the world, extending over from eight to ten months. He proposes a considerable stay in Buitenzorg, Java, visiting India on his way, and afterwards China and Japan, Honolulu and North America. Prof. K. Goebel, of Munich, is also starting, this autumn, on a botanical journey to Australia and New Zealand.

THE banquet of the Chemical Society to those of its past-Presidents who have completed fifty years' fellowship of the Society, which was postponed last June owing to the lamented death of the senior past-President, Lord Playfair, is now arranged to take place on Friday, November 11, at the Hôtel Métropole. The past-Presidents who will then be entertained are—Sir J. H. Gilbert, Sir E. Frankland, F.R.S., Dr. A. W. Williamson, F.R.S., and Dr. J. H. Gladstone, F.R.S.

PROF. S. SCHWENDENER, of the University of Berlin, has been made a Knight of the Order *pour le mérite* in the class of science and art. We learn, from the *Botanical Gazette*, that the Order was conferred by Frederick the Great, as a mark of distinction for military service; but the statute was revised in 1842 by Frederick William the Fourth, to include scientific men and artists of distinction. The latter class is limited to thirty Germans and thirty foreigners. The order is practically conferred by vote of the members. Prof. Schwendener is the only botanist who has been elected.

UPON the nomination of the Director of Kew Gardens, Mr. C. A. Barber has been appointed Government Botanist at Madras, in succession to the late Mr. M. A. Lawson.

THE Welby Prize of 50*l.*, offered for the best essay on "The causes of the present obscurity and confusion in psychological and philosophical terminology, and the directions in which we may hope for efficient practical remedy," has been awarded to Dr. Ferdinand Tönnies, of Hamburg.

AT the national observatory upon the Pic du Midi, a few days ago, two busts of General Champion de Nansouty and the engineer, M. Vauvenet, the founders of this useful meteorological establishment, were unveiled. M. Mascart, to whose suggestion the erection of the busts is due, and M. Baillaud, director of the Toulouse Observatory, delivered addresses to an audience of about five hundred persons who had assembled in the observatory.

THE handsome amphitheatre at the new Sorbonne has inscribed on the ceiling (says the *Chemist and Druggist*) the names of forty-five illustrious chemists. England is well represented by Cavendish, Priestley, Wollaston, Daiton, Davy, Faraday, Graham, and Grice—eight in all. The twenty-six French names are Lavoisier, Berthollet, Lefebvre, Proust, Vauquelin, Thénard, Gay Lussac, Dulong, Chevreul, J. B. Dumas, Desormes, Balard, Boussingault, Pelouze, Laurent, Gerhardt, Regnault, Péligot, Cahours, Ebelmen, Fremy, Wurtz, Henri St. Clair Deville, Debray, and Pasteur. Sweden is represented by Scheele and Berzelius, Russia by Zinin and Butlerov, Belgium by Stas, Switzerland by De Marignac, and Germany by Mitscherlich, Wöhler, Liebig, Kolbe, and Kekulé.

SIR WILLIAM MACCORMAC, BART., and Sir Francis Laking have been appointed Knights Commander of the Royal Victorian Order, and Mr. A. D. Fripp and Fleet-Surgeon A. G. Delmege

have been appointed Members of the Fourth Class of the same Order, in recognition of their services in connection with the recent accident met with by H.R.H. the Prince of Wales. The Royal Victorian Order is bestowed upon "such persons, being subjects of the British Crown, as may have rendered extraordinary, important, or personal service to Her Majesty, her heirs and successors, and who have merited Her Majesty's royal favour."

THE Harveian Oration will be delivered by Sir Dyce Duckworth on Tuesday next, at the Royal College of Physicians. The Bradshaw Lecture will be delivered by Dr. W. M. Ord on Thursday, November 10. The Goulstonian Lectures will be given next year by Dr. G. R. Murray, who has taken for his subject the Pathology of the Thyroid Gland. The Lumsian Lectures for next year will be given by Dr. Samuel Gee. The Croonian Lecturer for 1899 is Prof. Bradbury, and for 1900 Dr. F. W. Mott, F.R.S.

A MEETING of the Institution of Mechanical Engineers will be held on Wednesday and Thursday evenings, October 26 and 27, at the Institution of Civil Engineers, Great George Street, Westminster. The chair will be taken by the president, Mr. Samuel W. Johnson, at half-past seven p.m. on each evening. The following papers will be read and discussed, as far as time permits—"Electric installations for lighting and power on the Midland Railway, with notes on power absorbed by shafting and belting," by W. E. Langdon; "Results of recent practical experience with express locomotive engines," by Mr. Walter M. Smith; "Mechanical testing of materials at the locomotive works of the Midland Railway, Derby," by Mr. W. Gadsby Peet.

A CIRCULAR informs us of a proposal to place in Corsick Parish Church, by half guinea subscriptions, a suitable memorial to the memory of Prof. James Clerk Maxwell. There is already in the church a memorial to the memory of his father, John Clerk Maxwell, by whose influence and exertions the church was originally built. "This church," we read, "is chosen for the memorial, as the Professor's connection with it through life was very close. He was led to it as a child by his father, taught in its Sabbath School; was ordained an elder within its walls, and acted as such up to the time of his death; gave liberally towards its endowment, and the first and largest subscription towards the manse; was a trustee of the church and properties; and otherwise interested himself in its behalf." Subscriptions for the memorial may be sent to the Rev. George Starrock, The Manse, Corsick, by Dalbeattie, N.B.

THE fifth International Congress of Hydrology, Climatology and Medical Geology, was held during last and part of the present week at Liège, Belgium, under the patronage of H.R.H. the Crown Prince of Belgium, and the Presidency of the Minister of Agriculture. The Congress was well attended by representatives of various nationalities. Many important communications were read and discussed in the various Sections, but the most interesting was an address given before the whole Congress by Prof. Walther Spring, Professor of Chemistry at the University of Liège, on the colours of natural waters. Prof. Spring showed experimentally that the true colour of pure water is blue as in the Lake of Geneva, and that this colour is the colour proper to the water, and is not due to a mere reflection from the surface, nor from suspended particles in the water. When pure water has a very slight cloudiness, due to the presence of finely divided nearly white or colorless particles in suspension, even if these are absolutely colorless, as in the case of very finely divided rock crystal, a yellow tint is given to the water, which, together with the natural blue proper to the water itself produces a green colour, as in the cases of the Lakes of Neuchâtel and of Constance. He remarked that it had

been noted by various observers that the water of certain lakes usually green becomes occasionally absolutely colourless, and this he showed was due to the washing into the lakes of a fine mud of a reddish tint due to oxide of iron, which neutralises the green colour of the water, rendering it for the time being perfectly colourless. In connection with the Congress, interesting excursions were made to visit the bathing establishments, and to inspect the sanitary arrangements of Ostend and Middelkerke, Spa, Chandfontaine, and Aix-les-Bains. The Sanitary Institute was represented by Dr. Corfield, the Professor of Hygiene and Public Health at University College, London, who was elected an Honorary Vice-President of the Congress, and was also appointed the English Member of an International Committee which was formed for the purpose of inquiring into the means to be adopted for the preservation of the purity of the sources of natural mineral waters.

A COMPLIMENTARY dinner was given to Prof. Virchow at the Hôtel Métropole on Wednesday in last week. The chair was occupied by Lord Lister, and more than two hundred representatives of medical science and practice were present. Lord Lister, in proposing the toast of the evening, dwelt upon the versatility of the genius of the distinguished guest, his eminence as a pathologist being equalled by his reputation as an anthropologist and antiquarian. He referred particularly to Virchow's "Cellularpathologie," which work, he remarked, "swept away the false and barren theory of a structureless blastema, and established the true and fertile doctrine that every morbid structure consists of cells which have been derived from pre-existing cells as a progeny. Cellular pathology is now universally recognised as a truth. Even those morbid structures which deviate most from the normal structure are known to be derived as a progeny from normal tissue—from normal cells, driven to abnormal development by injurious agencies." In acknowledging the toast, Prof. Virchow made allusion to Huxley and his work in these words: "I have been touched by the confidence you have placed in me in choosing me to renew the remembrance of the great investigator whose commemoration we have just been celebrating. My task the other day demanded that I should demonstrate Huxley's influence upon the development of medical science. To-day I wish to emphasise that his merits in anthropological and ethnological respects are so great in the eyes of German investigators that they alone would suffice to procure immortal reverence for his name. We shall not cease to follow in his footsteps and to defend the place which he has assigned to man in nature. Together with you we will try to clear up in every direction the biological history of man. May this task still further confirm and strengthen the solid union of English and German science. May the corporations of Great Britain and Ireland, which form a bulwark of medical science and practice that has remained unshaken for centuries, continue to give the world by teaching and example a guarantee that the results of our science may benefit mankind in an ever increasing degree."

INOCULATION against plague has been accomplished on a very large scale at Hubli. The present population of Hubli is about 40,000, and a correspondent of the *Times of India* reports that up to September 7, 35,000 had been inoculated as a protection against plague, while about two-thirds of this number had been inoculated twice. Out of the whole proportion, therefore, there only remained about 5000 people who had not been inoculated at all; and by far the greater number of deaths which occurred were amongst these people. The returns for the first week in September show amongst 32,000 inoculated persons 69 attacks, and amongst 8500 uninoculated 417 attacks, which facts speak for themselves. The chief medical officer, Dr. Leumann, is writing a report on the results which he has obtained from

inoculation, and this ought to prove most interesting not only to those who are connected with plague, but to all the races who live in India. It is to be hoped that the report will be widely distributed, in order that the practical proofs which have been obtained may become the means of giving confidence to the wavering, and to those who at present regard the system of inoculation with fear, and are disposed to treat it with resistance.

A TRIBUTE to the genius of Lord Kelvin is paid by Prof. Oliver Lodge in the form of an article in the *Liverpool Daily Post* (October 4). After describing some of the ingenious devices and instruments which have made Lord Kelvin's name known to the public, Prof. Lodge refers to his more purely scientific work in the following terms:—"The modern theory of electricity, developed so brilliantly by Clerk Maxwell, was begun by him. The science of thermodynamics owes much to him; the theoretical laws of thermoelectricity were wholly worked out by him; and to him long ago is due the theory of those electric oscillations which were elaborated practically by Hertz, and have recently been exciting some popular interest as affording a method of wireless telegraphy. In the higher regions of optics also he has worked much, and in his Baltimore Lectures and elsewhere has striven to unveil the mystery of the reconnection between ether and matter, as revealed in the facts of radiation, fluorescence, phosphorescence, selective absorption, and dispersion. The definition and the experimental determination of the absolute zero of temperature are both due to him. The vortex theory of matter constitutes one of his most brilliant but incompletely worked out speculations. The kinetic theory of its elasticity and rigidity is a definite contribution to that view of the physical universe which seeks to resolve the whole of merely material existence into the two fundamental entities—ether and motion. Let any one ask what is the size of an atom, and he is referred to Lord Kelvin. Let him ask what is the age of the earth, and if he mean anything definite by this question—if he mean, for instance, what time has elapsed since the earth was a molten mass beginning to cool, it is again to Lord Kelvin that he must go. And then the tides, all the higher mathematical work on the tides, with their various causes and perturbations, is based on Kelvin's pioneering work, and to him all writers on this abstruse subject look up and defer as their master." The words in which Prof. Lodge concludes his article glow with appreciation. They are:—"Happy in the circumstances of his education, pertinacious in his unwearied industry, and undistracted by other interests from a constant devotion to definite dynamical science, narrow perhaps in some of its aspects, but all the more intense for that, he stands before us now a monument of human power and influence, one of the benefactors of the human species, one who has been happily preserved with hardly diminished energy for nearly sixty years of peaceful epoch-making work, one on whom posterity will heap high honours, and will regard with feelings of envy us of the present generation who are still illuminated by his living presence."

ON account of its practical importance, the influence of the chemical composition of a glass upon its coefficient of expansion has attracted the attention of several workers, more especially Fizeau, Schott, Châtenet, and Grenet. In the current number of the *Moniteur Scientifique* is an interesting *résumé*, by M. A. Granger, of the results obtained up to the present in this very complicated field. The simple rule tentatively proposed by Schott, that the expansion follows an additive law, is only approximately followed in a few cases, as quite a considerable number of substances, such as the oxides of lead, calcium, manganese, aluminium, and boron, possess the property of lowering the dilatation when added in small

quantities, and raising it when the proportion is increased. The addition of either potash, soda, lithia, fluorspar, lime, or calcium phosphate raises the coefficient of expansion of a glass, but with the exception of the last, which may be added up to 20 per cent., not more than 8 per cent. can be used. For proportions higher than this, the glass either refuses to take up any more, or else becomes devitrified and opaque. Calcium borate, oxide of iron, alumina, and silica have the effect of lowering the coefficient of expansion, alumina being especially active in this respect.

THE following neat result in the dynamics of impact is proved by Ingegneri D. De Francesco in the *Rendiconto* of the Naples Academy for July:—In the impact of two perfectly smooth solid bodies, the kinetic energy due to the velocities lost is a minimum compatibly with the final value of the difference of normal velocity of the points of contact. It is to be observed that the function which De Francesco proves to be a minimum is not the actual kinetic energy lost by impact, but a quadratic function of the differences of velocities before and after impact of the same form as the kinetic energy. The theorem is somewhat analogous to several of the "minimum" theorems given in the chapter on "Vis Viva" in Dr. Routh's familiar "Elementary Rigid Dynamics," and, to use a common way of speaking among mathematicians, the result "comes out in about a line."

We have received from Major General Schaw a copy of papers read before the Wellington Philosophical Society, on Australasian weather charts and New Zealand storms. Charts were exhibited illustrating types of summer and winter storms, and showing their progress eastward from the Great Australian Bight to New Zealand. The author urges that the phenomena exhibited in these charts of horizontal motion and atmospheric pressure, need for their elucidation a knowledge of the vertical circulation. With this object he has constructed a wind vane showing the wind direction both vertically and horizontally, and has made careful observations during several months. The observations showed that at times the upward or downward inclination prevails for hours, while at other times there may be for hours no regular deviation from the horizontal. The author refers to similar experiments by Prof. A. Klossowski at Odessa, which have been noticed in our columns, but makes no mention of those made by the Rev. M. Dechevrens at Zi-kai wei Observatory.

THE Report of the Meteorological Commission of the Cape of Good Hope for the year 1897 has been published. Barometric and thermometric observations are recorded from forty-six stations, and observations of rainfall from 336 stations. As an encouragement to continuous observations, the Commission presents to observers the instruments with which they have made a series of satisfactory observations for a period of not less than five years. Among the contents of the Report, in addition to the meteorological statistics and summaries, are useful notes for the guidance of observers, prepared by Mr. C. M. Stewart, Secretary of the Commission, and a short paper by Mr. A. Struben, upon the rainfall maps of South Africa, prepared by Dr. A. Buchan. The Report is illustrated by a map showing the distribution of summer and winter rainfall in percentages of the mean annual fall over the whole of South Africa, and by diagrams showing the mean monthly rainfall in each division, and the departures from the means of 1885-94. Another report of meteorological observations lately received contains the results of observations made during 1897 in the four Government observatories at Bangalore, Mysore, Hassan, and Chitaldrug, under the direction of Mr. J. Cook. A comparison is made between the results for 1897 and the means of the weather elements at these places during the last five years.

A NOVEL plan has recently been carried out at the Avonmouth Dock, at Bristol, for increasing the capacity of the lock so as to adapt it for the use of the larger vessels which, have for the last few years been coming into use. The length between the gates of the lock, as originally constructed, is sufficient to dock a vessel 425 feet in length; but the vessels now trading between Bristol and Canada are 465 feet long, and could therefore only enter and leave the dock at spring tides. To provide for their entering at all tides, the useful length of the dock has been increased by the adoption of a floating steel caisson which fits into grooves cut in the masonry of the lock walls beyond the outer gates, and which serves the same purpose as the gates, only giving an increased length to the space available for locking of 40 feet. This caisson is 70 feet long, 30 feet wide, and 46 feet high. When the vessel has entered the lock, the caisson is floated from its berth and placed in the grooves, the tanks are then filled with water sufficiently to sink it on to its sill. When the locking is completed, the water is pumped out, and the caisson floated back to its berth. The steamer *Montross*, which arrived from Canada a few days since with a large cargo of provisions, on a snap tide, and which is 465 feet in length, was the first vessel to be docked by the aid of the caisson.

THE Report of Dr. D. Prain, the Director of the Botanical Survey of India, for the year 1897-98, is largely occupied by a continuation of Prof. Woodrow's Flora of Western India. He records the botanical explorations which have been made during the year of portions of Assam and Burma, in the latter of which great assistance was rendered by Lieut. E. Pottinger, R.A.

A NEW edition of Mr. C. J. Woodward's "Arithmetical Chemistry," Part I, has been published by Messrs Simpkin, Marshall, Hamilton, Kent, and Co., Ltd. The book has been rewritten, with additions in the form of hints and suggestions for experimental work as a basis for the lessons. Elementary students of chemistry are thus instructed in laboratory methods, as well as given numerous arithmetical problems which will help to make them understand the value of quantitative work.

VOL. 1 No. 2 of the *Records of the Botanical Survey of India* is entitled a "Note on the Botany of the Kachin Hills north east of Myitkyina." It is, however, more than a "note," consisting of a record of the results of Lieut. E. Pottinger's journey through this district of Burma. After some preliminary general notes on the Botany of the Kachin Hills by Lieut. Pottinger and Dr. D. Prain, a complete list is given of the Flowering Plants and Vascular Cryptogams collected, the district proving especially rich in Orchidaceae. A small map is appended.

MR. STANFORD has now concluded the arrangements for the completion of the re-issue of his "Compendium of Geography and Travel." The Europe volumes are in the hands of Mr. George G. Chisholm, who has finished Volume I, comprising the countries of the mainland (excluding the north-west), and has Volume II, covering the British Isles, Scandinavia, Denmark, and the Low Countries, in hand. The volumes on Central and South America have been entrusted to Sir Clements Markham and Mr. A. H. Keane, and they will be furnished with the usual maps and illustrations. Mr. Stanford hopes to complete the issue of the series in the course of 1899.

FROM the United States we have the following botanical publications of taxonomic interest:—Revision of the Mexican and Central American species of *Galium* and *Rubus*; and Diagnoses of New and Critical Mexican Phanerogams, by J. M. Greenman (Contributions from the Gray Herbarium of Harvard University); also Onagraceae of Kansas, by Prof. A. S. Hitchcock, with sketch-maps of the distribution of each species (in French and English, published at Le Mans). And

from Australia:—Contributions to the Flora of New Guinea, Contributions to the Flora of Queensland (Fungi); and Edible Fruits indigenous to Queensland; all by F. M. Bailey

AN elaborate illustrated catalogue of chemical and physical apparatus has been issued by Messrs. Reynolds and Branson, Ltd., Leeds. No less than three thousand separate pieces of apparatus are listed in the catalogue, and very many of them are illustrated. The large number of physical appliances and instruments included in the catalogue is an indication of the important part which instruction in physics now takes in science schools. Teachers of practical science, more especially those working in connection with the Department of Science and Art, will find the catalogue serviceable when considering the purchase of apparatus.

M. C. SCHUYTEN publishes in the *Bulletin* of the Belgian Academy a continuation of his researches on the double salicylates of certain metals and antipyrin. He now finds that the salicylates of magnesium, of manganese and of lead, as well as certain others previously investigated, give rise to compounds with antipyrin, while he has found it impossible to realise, under the same conditions, the formation of double salicylates of aluminium, of chromium, and of uranium and antipyrin. The case of lanthanum is reserved for future consideration. M. Schuyten calls attention to the instability of these compounds in which water easily promotes dissociation.

THE additions to the Zoological Society's Gardens during the past week include a Sooty Mangabey (*Cercopithecus fuliginosus*, ♀) from West Africa, presented by Mrs. Henry Lloyd; a Mozambique Monkey (*Cercopithecus pygerythrus*) from East Africa, presented by Mrs. Snowden; an Indian Wild Dog (*Cyon aukhensis*, ♂) from India, presented by Surgeon-Lieut. Colonel J. Duke; an Egyptian Jerboa (*Dipus aegyptius*) from North Africa, presented by Mr. David Devant; a Suricate (*Suricata tetradactyla*) from South Africa, presented by Mrs. Molteno; a Golden Eagle (*Aquila chrysaetos*), British, presented by the Rev. F. Foxhambert; a Black-headed Cuckoo (*Coccyzus melanocapilla*) from Demersara, presented by Master Bertie Standing; a Common Squirrel (*Sciurus vulgaris*) from Austria, presented by Mr. A. M. Wigram; a Puma (*Felis concolor*) from America, a Reticulated Python (*Python reticulatus*) from the East Indies, deposited.

OUR ASTRONOMICAL COLUMN.

VARIABLE STARS IN CLUSTERS.—American astronomers have, during the last few years, made great advance in increasing our knowledge relating to variable stars. Nor have they limited themselves to photographic surveys of variable stars of the ordinary type, but have been examining clusters of stars to detect variability. Prof. Bailey, who has been very successful in this direction, has just undertaken a systematic search which has led him to some most interesting results (*Harvard College Observatory Circular*, No. 33). This *Circular* informs us that the whole number of stars examined in the photographs was 19,050, of which 500 were found to be variable, thus representing a variability of about 3 per cent. This at first does not seem a very high percentage, but, as Prof. Pickering points out, "it does not follow, however, that clusters in general contain more variable stars than occur elsewhere, for, if we except the four clusters = Centauri, Messier 3, Messier 5, and Messier 15, which contain 393 variables, an average of 7 per cent., the remaining 19 clusters have 116 variables among 13,350 stars, or less than 1 per cent." Even clusters which are equally rich in stars show great differences in this respect: thus the great cluster in Hercules (Messier 13) has only two variables out of 1000 stars, while in Messier 3, of 900 stars, 132 are variable. Not only have variables in these clusters been detected, but their periods

and light curves are being carefully determined. In the case of the cluster = Centauri, which up to the present has received most attention, 150 photographs have been taken with the 13-inch, and already 10,000 measures have been made. Of the 9000 stars used in this cluster for comparison, 125 have been recorded as variable. The periods of 106 have been determined, and 98 of these have periods less than 24 hours, the largest range in variation being about 5 magnitudes; no star is included which varies less than half a magnitude. Prof. Pickering has divided these 98 variables into four classes, namely, those which have a very rapid rise to maximum, those like γ Aquilae with a secondary maximum, those whose times of increase and decrease are about equal, and lastly those which drop very suddenly from maximum to minimum. Attention is called also to the marked regularity in the periods. In referring to the kind of clusters in which variables have been detected, he says that up to the present time only such dense globular clusters as Messier 3, Messier 5, and the great cluster in Hercules have been found to contain them.

LARGE METEORS IN 1897 AND 1898.—Mr. W. F. Denning in the *Observatory* for the present month brings together a number of notes concerning fireballs and bright meteors which have been observed in England during the last year and a half. In many cases sufficient and accurate information was available to enable their real paths to be determined. The radiant-points which have been derived from these observations are in most cases, as he says, very interesting, as they suggest evidence of new showers or corroboration of others previously observed.

As we have on several occasions in this column pointed out the great necessity of obtaining accurate and complete information of the path of these roving bodies through our atmosphere, so that observations may be comparable with one another, it is encouraging to read, and Mr. Denning himself is the writer, that "it is clear . . . that this department is receiving more attention than formerly. It is hoped that this interest will continue to increase, and that the fortunate spectators of fireballs will never forget to record those all important features, viz. the direction and position of the flight amongst the stars and the duration of visibility."

REMINISCENCES OF AN ASTRONOMER.—Prof. Simon Newcomb continues in *The Atlantic Monthly* for September his reminiscences, from which we make the following few extracts. In one of his journeys to observe a total eclipse of the sun he went to Gibraltar, and one of the first things he did the morning after his arrival was to choose "a convenient point on one of the stone parapets for 'taking the sun,' in order to test the running of his chronometer. I had some suspicion as to the result, but was willing to be amused. A sentinel speedily informed me that no nights were allowed to be taken on the fortification. I told him I was taking sights on the sun, not on the fortification. But he was inexorable, the rule was that no sights of any sort could be taken without a permit." Needless to say Prof. Newcomb soon obtained the required permit, and was allowed to continue his sights without interruption.

Having some important work to do with regard to the motion of the moon, and the Franco-Prussian war being on at the time, Prof. Newcomb went to Berlin, and Naples to pass the winter, and to wait till the war was over, until he could visit Paris. Having arranged his baggage, and on his landing at Naples the Custom House officer should find anything that was subject to duty at the top of his trunk, the officer contemptuously threw the top things aside, and devoted himself to a search at the bottom. "The only unusual object he stumbled upon was a spy-glass enclosed in a shield of morocco. Perhaps a gesture or a remark on my side aroused his suspicions. He opened the glass, tried to take it to pieces, inspected it inside and out, and was so disgusted with his failure to find anything contraband in it that he returned everything to the trunk, and let us off."

Speaking of Prof. Anders, who "stands at the head of German astronomy," he says, "in him is seen the highest type of the scientific investigator of our time, one perhaps better developed in Germany than in any other country. The work of men of this type is marked by minute and careful research, untiring industry in the accumulation of facts, caution in propounding new theories or explanations, and, above all, the absence of effort to gain recognition by being the first to make a discovery." Journeying to Pulkova to visit Otto Struve, Prof. Newcomb relates many interesting reminiscences. After mentioning that

the Instruments which Struve designed sixty years ago still do the finest work of any in the world, he tells us that the air there "is remarkably clear, the entrance to St Petersburg, ten or twelve miles north, is distinctly visible; and Struve told me that during the Crimean war he could see, through the great telescope, when on the decks of the British ships besieging Kronstadt, thirty miles away." Towards the latter part of these reminiscences, Prof. Newcomb mentions his meeting with Hansen, "who was at odds with him on a scientific question," the question being that Hansen was the author of a theory that the further side of the moon is composed of denser materials than the side turned towards us. We must, however, leave our readers here to study this article for themselves for further details, as we have already extended this note beyond the usual limit.

THE CAPE OBSERVATORY REPORT.—Dr. Gill's report to the Secretary of the Admiralty of the work done at the Cape Observatory during the year 1897, shows the great state of activity which has pervaded the whole atmosphere of the observatory during the past twelve months. It will be remembered that Mr. McClean last year made a stay at the Cape to complete his spectroscopic survey of all stars down to 3.5 magnitude, his 20-degree prism being fitted on to the 12-inch astrophotographic telescope. Unfortunately Mr. McClean's magnificent gift to the observatory did not arrive from Dublin during his stay, as was expected, so that he was deprived of the pleasure of witnessing its erection. The observatory for this instrument is completed as far as possible, and is only now waiting for the arrival of the heavy portions of the telescope. The rising floor and its hydraulic machinery have been set up, and, as Dr. Gill says, "the whole has been admirably designed by Mr. McClean and Mr. Osbert Chadwick, . . . it was erected here under my personal supervision by Cape workmen, and acts to perfection." The plans for the new transit circle and observatory have been settled in complete detail, and both will be executed with as little delay as possible. The transit circle has been employed chiefly for observations of standard stars required for the reduction of measures of the Catalogue photographic plates. A system of double watches with this instrument was organised so that the observers would be ready to take up the fundamental meridian work with the new transit circle in 1900. Both the equatorials have been employed, and the 7-inch was chiefly used by Mr. Innes for observing the stars in four lists forwarded by Prof. J. C. Kapteyn. In this work a star of the eighth magnitude was discovered "having an annual proper motion amounting to nearly 9" of arc on the great circle, the largest proper motion yet known." Besides several uncatalogued nebulae, Mr. Innes has found no less than 128 new double stars. Many of our readers may not be aware that Mr. Innes is secretary, librarian, and accountant to the establishment, but "has applied himself to the revision of the Durchmusterung and other extra meridian work (which he has performed as a labour of love), in addition to the thorough discharge of his official clerical duties." To refer to the work accomplished and proposed for the heliometer, the observations of the zenith telescope, the state of current reductions, publications, time service, would make this note too long, so we will only confine ourselves, in conclusion, to the fact that proposals have been sent forward for erecting a suitable building for a physical laboratory and accommodation for records and astrographic work.

ZOOLOGY AT THE BRITISH ASSOCIATION.

ALTHOUGH the foreign zoologists who had attended the International Congress at Cambridge a week before did not stay on for the British Association meeting, as had been expected, still the attendance at Section D was good, and many of the papers were of an interesting character. The number of papers was not large, so the Section did not meet on Saturday and Wednesday.

Prof. Weldon's presidential address gave a useful popular discussion of some of the principal objections which are urged against the theory of Natural Selection, and showed (1) that the law of chance enables one to express easily the frequency of variations among animals; (2) that the action of Natural Selection upon such fortuitous variations can be experimentally measured; and (3) that the process of evolution is sometimes so rapid that it can be observed in the space of a few years.

The Section did not sit in the afternoon, but a Biological Exhibition at the Clifton Zoological Gardens was opened at three o'clock by Sir John Lubbock.

Friday, September 9.—The following papers were taken:—Prof. E. B. Poulton, on the proof obtained by Marshall that *Præcis octavia natalensis* and *P. seaniensis* are seasonal forms of the same species. The specimens were exhibited.

Mr. F. Galton, on photographic records of pedigree stock. This was for the purpose of urging the systematic collection of photographs and information as to pedigree stock. Galton's ancestral law proves the importance of a much more comprehensive system of records than now exists. A breeder ought to be in a position to compare the records of all the near ancestry of the animals he proposes to mate together in respect to the qualities in which he is interested. More especially he ought to have access to photographs, which indicate form and general attitude far more vividly than verbal descriptions. Mr. Galton considers that every important stallion or bull should have a pamphlet all to himself, with photographs of his ancestry and with appropriate particulars about each of them. Mr. Galton, finally, proposes a scheme for the consideration of societies which publish stud books.

Mr. W. Garstang, on the races and migrations of the mackerel. From the examination of a large number of mackerel Mr. Garstang is able to distinguish the following three races:—

(1) American, (2) Irish or Atlantic, and (3) North Sea and Channel. Each of these races, he considers, does not wander far from its own coast in winter, and does not mix with the other races, but merely moves out into deeper water. Mr. Garstang also gave, along with Mr. H. N. Dickson, an account of the connection between the appearance of mackerel and the changes of sea temperature in spring and autumn. Whether the movements of the mackerel are determined directly by the temperature or indirectly through food was left unsettled, but the authors proposed a more detailed biological and physical investigation of the English Channel.

Prof. A. B. Macallum gave a short paper calling attention to points in the microchemistry of cells. A report was presented by the Committee on Zoological Bibliography and Publication, and also one by the Index Animalium Committee, giving an account of Mr. Sherborn's work at the Natural History Museum. The Canadian Biological Station Committee, appointed last year at Toronto, reported in favour of a floating station to be established in the Gulf of St. Lawrence for five years. Their application to the Dominion Government for an appropriation for construction and maintenance has been granted.

The report from the Plymouth Marine Biological Laboratory contained an account by Mr. G. Rehner of his algological work, by Mr. F. W. Gamble on his investigation of the nerves of *Arenicola*, *Nereis*, and other Polychaeta by the methylene blue method, and by Prof. Hickson on the embryos of *Aleocyonium* collected by Mr. Wadsworth.

The Committee on the Zoology of the Sandwich Islands stated that work was in progress, and that they hope to be able soon, with the aid of the Royal Society and the Bishop Museum in Honolulu, to publish a volume of investigations.

Dr. Arthur Willey's paper "On the phylogeny of the Arthropod amnion" stated that the importance of the problem lies in the fact that the principle which will account for the amnion of insect embryos is the same as that which has been applied by Prof. Huxley to the mammalian amnion.

The insect amnion is not congenetic and is not due to mechanical causes, as is the prevailing impression, but it is of phyletic significance. The material which supplied the necessary data for coping with this problem consisted of the embryos of a species of *Peripatus* (*P. novae britanniae*) which Dr. Willey found in New Britain last year. These embryos possess a remarkable trophic organ, the epidermal layer of which is called the trophoblast, and the latter is the forerunner of the serosa of insect embryos—the serosa being the essential structure in connection with the embryonic membranes of insects, the amnion being accessory or incidental to the serosa.

The report from the Naples Zoological Station, in addition to the usual statistical information as to the progress of the station, contained accounts by the three naturalists who have occupied the British Association table during the year as to their special work. Mr. J. F. Gemmill investigated the pseudobranch and the intestinal canal of *Teleostei*. Mr. H. M. Vernon writes on the relations between marine animal and vegetable life in aquaria; and on the relations between the hybrid and parent

forms of echinoid larvae. Mr J Parkinson worked at the variation of species of *Cardium*, *Donax*, and *Tellina*. The object of Mr Vernon's interesting work was to determine how the nitrogenous matter excreted by marine animals into the water is removed, and what parts the various forms of vegetable life and other agencies play in the process. Bacteria are of importance. It was found that the pipes conducting the water from the reservoirs to the rooms were coated internally with a layer of bacterial slime, and that in its passage along these pipes the water underwent considerable purification. Probably in marine aquaria a more powerful purifying influence than the bacterial is exerted by the diatoms and minute algae.

An interim report was presented by the Committee on Bird Migration in Great Britain; and the Rev T R R Stebbing discussed the report of the International Congress on Nomenclature.

The final report of the Oyster Committee was presented by Prof. W. A. Herdman, who gave an account, illustrated by lantern slides, of the chief conclusions arrived at. The report ends with the following recommendations:—

(a) That the necessary steps should be taken to induce the oyster trade to remove any possible suspicion of sewage contamination from the beds and layings from which oysters are supplied to the market. This could obviously be effected in one of two ways, either (1) by restrictive legislation and the licensing of beds only after due inspection by the officials of a Government Department, or (2) by the formation of an association amongst the oyster-growers and dealers themselves, which should provide for the due periodic examination of the grounds, stores and stock, by independent properly qualified inspectors. Scientific assistance and advice given by such independent inspectors would go far to improve the condition of the oyster beds and layings, to reassure the public, and to elevate the oyster industry to the important position which it deserves to occupy.

(b) Oysters imported from abroad (Holland, France, or America) should be consigned to a member of the Oyster Association, who should be compelled by the regulations to have his foreign oysters as carefully inspected and certificated as those from his home layings. A large proportion of the imported oysters are, however, deposited in our waters for such a period before going to market that the fact of their having originally come from abroad may be ignored. If this period of quarantine were imposed upon all foreign oysters, a great part of the difficulty as to inspection and certification would be removed.

(c) The grounds from which mussels, cockles and periwinkles are gathered should be periodically examined by scientific inspectors in the same manner as the oyster beds. The duty of providing for this inspection might well, we should suggest, be assumed by the various Sea Fisheries Committees around the coast.

Dr H. Lyster Jameson exhibited examples of a race of protectively coloured mice that inhabit a sandy island in the Bay of Dublin, known as the North Bull. A considerable percentage of these mice are distinctly lighter in colour than the ancestral type (*Mus musculus*, Linn.). Every possible intergradation, however, occurs between the typical house mouse and the palest examples. Mr Jameson considers the marked predominance of sand-coloured examples as due to the action of natural selection. The hawks and owls, which frequent the island and hunt by "sight," are the only enemies the mice have to compete against, and they most easily capture the darkest mice; that is to say, the mice that contrast most strikingly with the colour of the sand; and thus by the weeding out of the dark-coloured examples a protectively coloured race is becoming established, which, however, has not yet settled down into the comparative stability which usually characterises species.

A reference to old charts and Parliamentary papers has shown that this island first came into existence about a century ago, consequently it is in this case possible to fix a time limit within which the race in question has been evolved.

Monday, September 12.—The Section opened with an interesting account, by Prof. Poulton and Miss C. B. Sanders, of an experimental inquiry into the struggle for existence in certain common insects. A large number of lepidopterous pupae were exposed under various conditions at Oxford, in Switzerland, and in the Isle of Wight, in order to test by experiment the amount of destruction by birds and other enemies, and also to determine what amount of protection was afforded by coloration. The results showed that there is a heavy death-rate in the pupal condition, and apparently that there is a greater destruction of pupae at Oxford than in Switzerland. An interesting discussion fol-

lowed, in which Sir John Lubbock, Prof. Lankester and Prof. Meldola took part. Miss Sanders described and demonstrated with specimens the actual details of the experiments and observations.

Prof. Lloyd Morgan followed with a paper on animal intelligence as an experimental study, which dealt largely with the results of Mr. Thorndike's experiments in America with cats. It was shown that the cats, in opening the doors of ingeniously devised cages, learned gradually by experience, and were not able to profit by imitation. This performance of purposive acts, learned as the result of chance experience, was characterised as intelligent in contradistinction to rational. Prof. Morgan expressed the opinion that without the record of the genesis of an intelligent action observation and anecdote of animal intelligence are of little importance, and in answer to Sir John Lubbock, and others who spoke in the discussion, he stated that the advantage of simple experiments, such as those of Thorndike, over observations, is that the results can be readily expressed in curves.

Dr A. J. Harrison read a paper on his own observations in the Clifton Zoological Gardens, on the so-called fascination of snakes. The animals dealt with were pythons, both adult and young, and it was shown that in captivity, at least, there was no evidence that they possessed the power of fascinating their living prey, such as hens, ducks and rabbits.

Prof. O. C. Marsh gave a paper on those families of the Dinosaurs, which he has called Saurapoda—such as *Cetiosaurus* and its allies—upon which he has a memoir ready for publication.

Dr. Masterman read a paper by Prof. McIntosh on the scientific experiments to test the effects of trawling in the waters of Scotland from 1886 to 1897. The areas dealt with were St. Andrews Bay, the Firth of Forth, and the Moray Firth, and Prof. McIntosh gave his reasons for dissenting from the conclusion drawn from the work of the Fishery Board for Scotland, that the closure of areas against trawlers had led to an increase in the fish population.

The remaining papers were—A new theory of retrogression, by Mr. C. A. Reid, the structure of nerve cells, by Dr. G. Mann; and a circulating apparatus for use in researches on colour physiology and other purposes, by Messrs F. W. Gamble and W. F. Keeble.

Tuesday, September 13.—The following papers were taken—Mr R. I. Pocock, on musical organs in spiders, Dr A. T. Masterman, on the origin of the vertebrate notochord and pharyngeal clefts, Prof. Ch. Julin, on "Le développement du cœur chez les Tuniciers—quelques considérations sur la phylogénie des Ascidies zoologiques"; Mr. W. E. Hoyle, on Dr. Field's card catalogue of zoological literature, Mr. F. A. Bather, on the classification of the *Pelmatozoa*; Prof. A. B. Macallum, on the detection of phosphorus in tissues; and two reports of Committees, one on the physiological effects of peptone and its precursors when introduced into the circulation, and the other on the exploration of caves in the Malay Peninsula.

Prof. Julin in his paper dealt with the formation of the heart from the epicardium and its homology with the notochord. He showed reasons for regarding *Dystoplia* as a central form linking the other compound ascidians to the simple ascidians through the Clavelinidae.

The Peptone Committee report that their experiments make it appear probable that peptones and albumenoses are not wholly foreign substances to the circulating blood. It is, however, uncertain to what extent any given substance introduced into the circulation is again recoverable from the urine, and how long such substances can retain their identity after being so introduced. Anti-peptone seems to remain in the system to a much greater extent than any of the other substances employed.

As Section I did not meet this year, but was supposed to be incorporated with D, several of the papers and reports—such as the one last mentioned—were of a physiological nature.

GEOGRAPHY AT THE BRITISH ASSOCIATION.

THE Geographical Section at Bristol was as a rule well attended, and on one occasion crowded; but, as happens too frequently, the audience had a tendency to vary inversely as the scientific value of the communications submitted to it. Yet on the whole the twenty-five papers read were of high quality, and some of them represented original work in research as well as in travel. The President, Colonel George Earl

Church, formerly of the United States Army, gave an address full of original observations on the central parts of South America, in the course of which he traced the origin of the main features of that continent. This address as printed is enriched with a series of maps and diagrams.

Seven important papers were read on various branches of physical geography, most of them being illustrated by lantern slides. Mr. Vaughan Cornish discussed wave-forms, giving the preliminary results of a research in which he is engaged on the phenomena of waves in water, air, and drifted sand. The results were made clear by a large number of carefully selected photographs and diagrams.

Mr. H. N. Dickinson gave a brief account of his work on the salinity and temperature of the North Atlantic, which promises to produce results of great value. His paper described the first results of a discussion of observations of surface temperature made in the North Atlantic, during the two complete years 1895 and 1896, by the captains and officers of merchant ships. The captains of a number of the vessels also collected daily samples of surface water, and the densities of these, numbering about 5000 in all, have been determined by chlorine titration. The material has been found sufficient to allow of the construction of charts showing the distribution of temperature and salinity over a large part of the area during each of the twenty-four consecutive months. The series, which is the first of its kind, shows the progressive changes in the manner of synoptic charts, and provides the data necessary for extending the work recently done in and around the North Sea, in connection with sea fisheries and long period weather forecasting. Specimens of the maps were shown on the screen.

Dr. K. Natterer, of Vienna, submitted the oceanographical results of the Austro-Hungarian Deep-Sea Expeditions in the Eastern Mediterranean, Sea of Marmora, and Red Sea. He referred especially to his own chemical observations and the deductions made from them. Of these the most striking was the presumption that the salt deposits of arid regions surrounding a deep sea were due to the evaporation of sea-water raised by capillarity through the substance of the rocks.

A report by Mr. A. G. F. de la Roche was presented on behalf of the Committee for the investigation of the climatology of Africa. The efforts of this Committee during the last seven years have resulted in inducing a number of the African colonial governments to institute regular meteorological observations, and the Committee feels that it is no longer necessary to supply instruments to unofficial observers, although several of the sets supplied to missionaries and others have led to the compilation of important records.

Dr. J. W. Gregory discussed the theory of the arrangement of oceans and continents on the earth's surface in the light of geological and physical observations. He pointed out that Elie de Beaumont's famous scheme attached undue importance to linear symmetry and was too artificial. It led, however, to the tetrahedral theory of Lowthian Green, which regards the world, not as shaped like a simple tetrahedron, but as a spheroid slightly flattened on four faces. Such flattenings occur on hollow, spherical shells, when they are deformed by uniformly distributed external pressure. The oceans would occupy the four depressions thus produced, and the land masses occur at the angles and along the edges. The existing geographical arrangement is in general agreement with this scheme, for as the tetrahedron is hemihedral the assumption that the lithosphere is tetrahedral explains the antipodal position of land and water, the excess of water in the southern hemisphere, and the southward tapering of the land masses. The main lines of the existing system of fold mountains have a general agreement with the arrangement of the edges of a tetrahedron. Some striking deviations occur, but are explicable by the variations in the composition of the lithosphere, and the existence of impressive blocks of old strata which have moulded the later movements. The lines of the old fold-mountains of the Hercynian system may have been tetrahedrally arranged, with the axes occupying different positions from those of the great Cimmerian mountain system. So far, however, there is no completely satisfactory theory of geomorphology, for which we must wait for further information as to the distribution of land and water in successive epochs of the world's history.

Two important papers on earthquake phenomena were read—one by Prof. J. Milne, F.R.S., on the methods and utility of seismological research, the other by Mr. R. D. Oldham, on the great Indian earthquake of June 12, 1897,

which was the largest and, with a few possible exceptions, the most violent of which there is any record. The area over which the shock was sensible was not less than 1,750,000 square miles, while the focus occupied an area of 200 miles in length and 50 miles in width. Landfalls on an unprecedented scale were produced in the Garo and Khasia hills, and in the Himalayas north of Lower Assam. A number of lakes have been produced by changes of level due to the earth-movements by which the earthquake was caused, and the mountain peaks have been moved both vertically and horizontally. Monuments of solid stone and forest trees have been broken across by the violence of the shaking they have received. Communications of all kinds were interrupted; bridges were overthrown, displaced, and in some cases thrust bodily upwards to a height of as much as 20 feet, while the rails on the railways were twisted and bent. Earth fissures were formed over an area larger than the United Kingdom, and sand rents, from which sand and water were forced in solid streams to a height of 3 to 5 feet above the ground, were opened in incalculable numbers.

Dr. J. Scott Keltie in a short paper on "political geography" laid stress on the way in which natural conditions determined the manner of the relations between land and people, and showed how changing economic conditions produced corresponding changes in political geography, e.g. the formation of such forms as spheres of influence and leased territories. A paper by Mr. G. G. Chisholm, on the impending economic revolution in China, enforced by a concrete instance of great practical importance some of the theoretical considerations brought forward by Dr. Keltie.

Mr. H. T. Crook, of Manchester, criticised the methods of selecting place-names for the Ordnance Survey Map, and brought forward several errors in the sheets of the new one inch map of the Manchester district. The paper gave rise to a lively discussion, in which Mr. G. F. Deacon supported the contention of the author; while Colonel Farquharson and Sir Charles Wilson, the present and late Directors-General of the Survey, fully explained the methods employed and showed the enormous difficulties with which the whole question of place-names is surrounded. They stated that the Survey always welcomed criticism, and that corrections were frequently made on the plates as the result of information sent by people in the localities when mistakes occurred. It was suggested that the public could aid in the production of good maps more effectively by communicating with the Survey Office than by writing critical articles in the press.

A group of papers submitted to the Section dealt with geographical developments of the future. Prof. Reclus brought forward his scheme for a great terrestrial globe on the scale of 1:500,000, or about 84 feet in diameter. The surface of this globe should exhibit the relief of the lithosphere on a true scale, and separate plates of it would be available for use as relief maps upon a surface showing the natural curvature. M. Reclus spoke with great eloquence of the scientific and educational advantages of his scheme, the initial cost of which, however, could not fall far short of 50,000*l.* In the discussion Sir Richard Temple spoke in support of the work being carried out, and a Committee of Section E was appointed by the General Committee to consider and report upon the scientific value of the proposal.

Prof. Patrick Geddes described an interesting experiment in the practical teaching of geography about to be tried in Edinburgh, where he is fitting up an "outlook tower" or geographical museum of a novel character. Thus the exhibition of the ground-floor centres round a globe with an outline survey of the main concepts of world geography—e.g. an incipient collection of maps and illustrative landscapes, an outline of the progress of geographical discovery and of map-making, &c. The first floor is devoted to the geography and history of Europe in correspondingly fuller treatment; the second is set apart for an outline geography and history of the English-speaking world, the United States having a room on the same level as the British Empire. On the third story is preparing a corresponding survey of Scotland, viewed at once as an historic and social entity and as an element of greater nationality; while the fourth story, naturally as yet in the most advanced state of preparation, is a museum of Edinburgh, though again not without comparison with Scottish and other cities. The flat roof bears a tower of culminating outlook with a camera obscura. Descending from the roof to the uppermost story, this succession and unity of the physical, organic and social conditions is better understood.

Thus the relief model of the site of Edinburgh brings indisputable light on the interpretation of the antique and the modern city, its military history or its industrial present, its medical eminence or its picturesque interest. Similar regional towers should be erected in all large towns. A tower as a memorial to Cabot was recently opened in Bristol, presenting some features which might be developed on the lines of Prof. Geddes' conceptions, but no reference was made to it at the meeting of Section E, nor was the Section invited to visit the tower.

Ballooning as an aid to geographical exploration was discussed by Captain B. Baden-Powell, of the Scots Guards, who outlined a well considered scheme for an experimental balloon voyage up the Nile valley, where the meteorological conditions are more favourable than those of the Arctic regions, and the chances of disaster more remote. Mr. Eric Stuart Bruce exhibited a method of flash signalling by means of an electric lamp enclosed in a transparent balloon, which he believes to be of special value in polar exploration.

Dr. H. R. Mill discussed the prospects of Antarctic research, tracing the historical changes of the Antarctic problem, and pointing out that the purely scientific importance of south polar exploration demands co-operation amongst simultaneous expeditions rather than consecutive work. He hoped that the definite refusal of Government to take up the work would now leave the way clear for the immediate organisation of a great expedition by the British nation to co-operate with the German expedition which has been planned for 1900.

While the characteristic of this meeting was undoubtedly the solid value and good discussion of the general papers, it in no way fell short of the meetings of preceding years in the interest and value of the records of personal exploration. Mrs. Bishop gave a remarkable paper describing her recent journey in the Yangtze valley, and summarising the geography of that important region. It was illustrated by a series of unique photographs taken by Mrs. Bishop herself. Mrs. Theodore Bent also contributed a paper describing her visit to Sokotra, in the course of which she made valuable observations. A Committee, with a small grant in aid of the further exploration of Sokotra by Dr. H. O. Forbes, was appointed by the Association.

Sir Charles Wilson gave an address on the Upper Nile region with reference to the recent conquest of the Sudan; and, in the absence through illness of the author, he also read a paper, by Sir T. H. Holdich, on Timb, which was splendidly illustrated by slides. Mr. C. W. Andrews, of the Natural History Museum, gave a preliminary account of Christmas Island in the Indian Ocean, where he has recently spent the greater part of a year. He found it to be an unpraised coral island, the coral limestone resting on a hard foraminiferous limestone, which in turn is based on basalt. The whole island is so densely jungle-clad that it could only be traversed at the rate of one mile per day, every yard having to be cut through the dense undergrowth. Captain G. E. H. Barrett Hamilton described a recent visit he had made to Karaginski Island and the mainland of northern Kamchatka, and Mr. O. H. Howarth added another to his important series of papers on the exploration of Mexico, dealing on this occasion with a journey from Mazatlan to Durango across the Sierra Madre.

It may be pointed out as a disappointing feature at the meeting, that no effort appears to have been made to place before the Section any account of the remarkable geographical position of Bristol with respect to site, immediate surroundings, or commercial position in the world.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

MR. W. BECKIE BURNIE has been appointed to the vacant Senior Demonstratorship in Electrical Engineering at the South-Western Polytechnic, Chelsea. Mr. Burnie has studied at the Nottingham University College; under Prof. Ayrton, at the Central Technical College; and under Prof. Weber, of Zürich.

DR. M. C. SCHUYTEN, rue van Luppen 31, Antwerp, invites teachers who are daily engaged in instructing children to make notes upon the characteristics of the minds of their pupils, and send them to him for incorporation in a work, to be published

by a special commission upon the psychology of the child from a pedagogic point of view.

THE foundation-stone of a new Science and Art School for Deptford was laid in New Cross Road on Saturday. The new school is the result of an amalgamation by the Charity Commissioners of two ancient charities—the Addey and the Stanhope—and the joint school is to be known as the Addey and Stanhope Foundation. The new building will cost for erection 10,000*l.*, and for furniture and fittings about 4000*l.*

A COURSE of twenty-four lectures and practical demonstrations on the theory and practice of photography, by Mr. W. J. Pope and Mr. A. A. Donald, commenced on Friday last at the Goldsmiths' Institute, New Cross. Mr. Pope is giving a course of twenty-eight lectures on metallurgy, and a course of laboratory instruction on methods of water analysis commenced on Wednesday, October 5. The course will extend over twelve evenings, and the students will obtain practice in the chemical methods ordinarily used to ascertain the degree of purity of water and its suitability for various manufacturing and domestic purposes.

IN an address delivered to the members of the London School Board on Thursday last, Lord Reay, the Chairman of the Board, remarked: "Training in physics is found to be preferable to chemistry, and the laboratories now in construction are, as a rule, so fitted as to be adapted to the teaching of physics rather than for specialised instruction of chemistry. Geography in the past has been taught too mechanically. Map drawing has been revived and greatly improved, but more attention should be given to physical geography, to the great phenomena of nature, to the laws influencing climate, productiveness of soil, &c. History should be connected with geography, and the lessons should be given in such a manner as to make history and geography illustrate each other."

THE Directors of Nobel's Explosives Company, Limited, after consultation with Dr. G. G. Henderson, Freeland Professor of Chemistry in the Glasgow and West of Scotland Technical College, have decided to give a prize tenable under the following conditions: (1) The prize to be 30*l.* and to be known as the "Nobel Company Prize." (2) The prize to be awarded annually, until further notice, to a student in the chemical laboratory of the Technical College, who has passed through the usual course of training in that laboratory, and who, in the opinion of the Professor of Chemistry for the time being, is qualified to prosecute research. (3) The holder of the prize to engage in research work in the chemical laboratory of the Technical College, under the direction of the Professor of Chemistry for the time being, for the period of one academical year. (4) The prize to be awarded by the Professor of Chemistry for the time being. In accepting the gift, the Governors of the College further resolved to grant a free studentship for one year in the laboratory to the Nobel Company's prizeman, thus raising the money value of the prize to about 50*l.* The example of Nobel's Company might profitably be followed by other chemical manufacturers.

THE Scotch Education Department has issued a circular in further explanation of the scheme of organised science instruction in various classes of schools recently proposed (see p. 408). The schemes proposed in aid of systematic instruction based upon the teaching of science, or in which science is a predominant element, are two—viz. (1) the scheme for higher grade (science) schools, and (2) the scheme for schools of science defined in the Science and Art Directory. The former is especially designed to apply to secondary departments, which, while possessing a distinct organisation, are connected with schools aided under the Education Code, which possesses the necessary equipment for giving practical instruction in science, and in which the predominant aim is intended to be scientific. It is thought that the scheme provides a course of instruction especially suitable for pupils leaving school at the age of fifteen or sixteen, who will in after life for the most part follow industrial or commercial pursuits. Having regard to the increasing importance of a thorough training in science, especially in large industrial centres, the circular points out that schools of science should by preference

be absolutely independent institutions, having their own premises, equipment, and staff, in which instruction in science can be carried to a much higher point than obtains at present, and it is hoped that such schools of science, in the proper sense of the term, will be before long established in the large towns. But for the present, on good cause being shown, the existing practice of recognising, as schools of science, the science sides or departments of secondary schools, will not be departed from. The science side must, however, be clearly separated from the classical or language side of such schools. In view of the presumably greater age of pupils in a secondary school, it will be required, as a condition of the continued recognition of a school of science, that a considerable proportion of the pupils shall proceed to the advanced course; and the inspectors will be directed to make strict inquiry into the reasons which prevent pupils who have entered upon the course, and are still in attendance at the school, from completing the curriculum.

SOCIETIES AND ACADEMIES.

PARIS

Academy of Sciences, October 3.—M. Van Tieghem in the chair.—The analysis of some commercial specimens of calcium carbide, by M. Henri Moissan. If calcium carbide is prepared from impure materials, it is liable to contain calcium phosphide and aluminium sulphide, both decomposable by water, giving hydrogen phosphide and sulphide respectively. In the residue left after treatment with water, besides lime, there is found calcium, iron, and carbon silicides, calcium sulphide, and sometimes graphite. Crystals of silica are also present, but a careful search for diamonds gave negative results in all the samples examined. The acetylene produced by the action of water upon the carbide contains traces of sulphur compounds other than sulphuretted hydrogen.—Increase of weight of the body, and the transformation of fat into glycine, by M. Ch. Bouchard. In the course of some observations upon the changes of weight in a man placed under such conditions that the only *ingesta* could be atmospheric air and the only *secreta* moisture and carbonic dioxide, a distinct gain of weight was observed. Repetitions were made confirming this, the gain being on one occasion as much as 40 grams per hour. After a discussion of the possible ways of accounting for this increase, the conclusion is drawn that the only probable explanation is to be sought in the conversion of fat into glycogen, according to the equation

Experiments made on animals fed with fatty diet confirmed this view.—On the distribution of farm manure, by M. P. P. Dehérain. An experimental study of the losses of ammonia and carbonic acid by farm manure exposed to intermittent currents of air.—Observations of the planet DQ Wuti (August 13), made with the large equatorial of the Observatory of Bordeaux, by MM. Rayet, L. Picart, and F. Courty.—On intercapulothoracic amputation in the treatment of malignant tumours of the upper extremity of the humerus, by M. Paul Berger. In both the cases operated on by the author a radical cure was effected, the recovery being very rapid. Out of forty-six cases of this operation on record, only two were attended with fatal results.—Observations of comets made at the Observatory of Rio de Janeiro, by M. L. Crula.—Observations of the 1898 Comet (Perrine-Chofardet), made at the Observatory of Besançon, by M. L. J. Gruey.—On a class of contact transformations, by M. E. O. Lovett.—On the preparation and properties of the double carbides of iron and chromium, and of iron and tungsten, by M. Percy Williams. A mixture of chromium oxide (200 gr.), iron (200 gr.), and carbon (70 gr.) is heated in the electric furnace for five minutes with a current of 900 amperes and 45 volts. The carbide can be isolated from the fused mass in metallic needles, having the colour of nickel. A double carbide of iron and molybdenum is obtained in a similar manner. The formulae of these compounds are $3Fe_2C \cdot 2Cr_2C_3$ and $Fe_2C \cdot Mo_2C$.—New combinations of phenylhydrazine with certain metallic salts, by M. Pastureau. Combinations of phenylhydrazine with $BiCl_3$, $Bi(NO_3)_3$, $ZnSO_4$, and $MnSO_4$ are described.—On the vivipary in an annelid (*Dolacacia conchurum*), by MM. Felix Mesnil and Maurice Caullery.—On the tactile impression due to the contact

of a succession of reliefs representing a mobile object in its different positions. With practice it is possible to rapidly recognise a relief by touch, and if a series of reliefs follow each other at a certain rate, the effect of movement is obtained. Thus the motion of the flight of a bird may in this way be imparted to the blind.

BOOKS, PAMPHLET, SERIALS, &c., RECEIVED.

Books.—Skigraphie Atlas, J. Poland (Smith, Elder).—Seismologie, J. Milne (K. Paul).—A Treatise on Dynamics of a Particle, Dr. E. J. THURSDAY, OCTOBER 20, 1898.

PEARY'S "NORTHWARD OVER THE GREAT ICE"

Northward over the "Great Ice" A narrative of life and work along the shores and upon the interior ice-cap of Northern Greenland in the years 1886 and 1891-1897 With a description of the little tribe of Smith Sound Eskimos, the most northerly human beings in the world, and an account of the discovery and bringing home of the "Savaksue" or great Cape York meteorites By Robert E. Peary, Civil Engineer, U.S.N. With Maps, Diagrams, and about eight hundred Illustrations. In two volumes. Pp. lxxv + 522 and xiv + 626 (London: Methuen and Co., 1898.)

IT may safely be said that the title-page is the dreariest in this book. It lacks the quaintness which enlivened the gossipy titles of the sixteenth century, and it does not altogether dispense with the necessity for a table of contents. The maps also are extremely disappointing, and it is to be regretted that the English edition at least was not provided with a well executed map of part of the polar regions on a fair scale, especially as Mr Peary repeatedly found errors in the existing charts which his observations enabled him to correct. The new work, however, has probably been postponed until the expedition on which Mr Peary is now engaged—the survey of the Arctic archipelago, north of Greenland—has been carried out. We are promised a full discussion by specialists of the various branches of science studied by the members of the various expeditions, the record of which fills these volumes. They profess only to give a popular account of the work accomplished, and they do this in a full and satisfactory manner. The almost innumerable illustrations differ in quality, but many of them are remarkably clear and some have an artistic beauty that is unusual.

The outward form of the book is like that of most books of popular travel, but within there are marked differences. The amounts of time occupied and of space covered were so large that the narrative had to be compressed (to the detriment of the printing towards the end), in order to get it into two volumes. Hence, as the author states, there was no room for padding. An excellent device is that of following each section describing an expedition with a summary of the objects and results. One result not mentioned is that Mr. Peary has obtained more experience of long-distance sledge-travelling with dogs, and of life at extremely low temperatures, than any other living man.

With regard to these Arctic journeys it is desirable to point out that they are the work of one man, an enthusiast determined to persevere in the attempt to accomplish his plans, but absolutely unfettered by the instructions or advice of others. The United States Government have done no more for him than to renew his leave with increasing reluctance, the scientific societies have supported him, but could only give very small money grants, a few private friends have done something to help forward the expeditions; but in every case the greater part of the funds has been provided by

the efforts of Mr. and Mrs. Peary themselves. All they have been able to make they have put into the equipment of the new expedition, and from a pecuniary point of view it is impossible that the labours of so many years of effort can meet with an adequate reward.

Mr Peary is very frank in expressing his opinion about himself, he bases his passion for Arctic travel mainly on sentiment, but the sentiment bears fruit in sober plans, laborious scientific researches, and a terse and mainly narrative of occurrences.

The object of the first journey in 1886 was "to gain a practical knowledge of the obstacles and ice conditions of the interior of Greenland, to put to the test of actual use certain methods and details of equipment, to make such scientific observations as may be practicable, and to push into the interior as far as possible."

The results were the attainment of a greater distance inland and a higher elevation on the inland ice than had been previously done by any white man, and a great deal of valuable experience as to equipment and methods. Mr Peary, on his return, drew attention to three lines along which the crossing of Greenland from west to east should be attempted, and he demonstrated that the attempt was practicable.

In 1888 Dr Nansen succeeded in crossing the south of Greenland from east to west, and accordingly Peary concentrated his attention on the northern routes, although it was not until the summer of 1891 that he was able to escape from official routine and resume exploration.

The objects of the 1891-92 expedition were the determination of the northern limit of Greenland overland, the possible discovery of the most practicable route to the pole, the study of the Smith Sound Eskimos, and the securing of geographical and meteorological data.

The results were highly satisfactory. The conditions of travel over the smooth elevated surface of the inland ice were worked out, one of the most interesting details being the use of an odometer or measuring wheel attached to a sledge, in order to give distances by dead reckoning. Another was to demonstrate the possibility of sleeping at the lowest recorded temperatures in the open air without either tent or sleeping bag. The inland ice was found to have the same shield shape in the extreme north as Nansen showed it to have in the south, and the surface was smooth and unbroken, except near the edges and where the glacier basins dipped to the north. The insularity of Greenland was determined to Mr Peary's satisfaction, grass was found growing, and musk-oxen feeding north of the ice-cap; and still further north beyond a narrow strait, low land was discovered free from ice. In addition, comprehensive meteorological and tidal observations were made at the base station on Ingfield Gulf, the shores of which were surveyed, and the tribe of Arctic Highlanders were exhaustively studied and photographed as no tribe of Eskimos had been before.

The expedition of 1893-94 set out with an ambitious programme. A large party was to cross the ice-cap to Independence Bay on the north-east coast, and there to divide: part going north in an attempt on the pole, part turning south to trace the unknown east coast of Greenland. It was a failure. Mr. Peary points out that the efforts he was obliged to make to raise funds prevented

him from exercising sufficient care in selecting his companions. He broke one of his own rules by taking too many, and the majority of them turned out totally unfit for the work. The climatic conditions, too, were very unfavourable, a succession of furious gales was encountered with temperatures down to -60° F., but before acknowledging defeat a magnificent effort was made to cross the ice-cap.

In 1894-95 Mr Peary remained in Greenland, whilst his wife, their little daughter, and the majority of his party returned to the United States. One white companion, Lee, and the negro servant, Henson, alone remained faithful, and in the spring of 1895 Peary and Henson, provided with insufficient supplies, once more made the long tramp across the inland ice, rising to over 8000 feet, and back again, 1200 miles in all, reaching the base with one surviving dog and no food. The hardships were severe, and it was impossible to extend the observations at Independence Bay beyond those made in 1892, but the effort was heroic. A visit to Cape York before returning was rewarded by the discovery of the sources of native iron which Sir John Ross heard of in 1818. They were found to be three large meteorites, and the summer trips of 1896 and 1897 were successful in bringing them back (see NATURE, vol. lvi., p. 132).

During these expeditions the knowledge of the Arctic regions had been greatly advanced by other explorers, and the drift of the *Fram* convinced Mr Peary that the only reasonable chance of reaching the pole was from the north of Greenland. To this purpose he now intends to devote himself, and his plan is to become for the time practically an Eskimo, living in snow igloos, and accompanied by a few picked families of the Smith Sound tribe, every individual of which he has come to know well. Experiments during his three winters in the far north have convinced him that it is quite practicable in good weather to travel with sledges during the Arctic night, although of course the greater part of his journeys will be done in summer.

Apart from the direct work of the Peary expeditions, great scientific advantages have accrued from the summer parties he has taken up in successive years. These included Prof Chamberlin of Chicago, Prof Heilprin of Philadelphia, Prof. Tarr of New York, and a large number of other specialists; and already some important monographs, such as those of Prof Chamberlin on Glacial Phenomena, have been published.

In meteorology there is one fact of great importance clearly demonstrated, which Nansen refers to as probably true in the account of his crossing of Greenland. It is that the wind always blows strongly outward from the interior. Once arrived at the summit level of the ice-cap, whether going east or west, Peary always found a strong favourable wind, enabling him to use sails on the sledges. The condensation of air by the extreme cold of the high plateau would naturally give rise to outflowing winds, and the question arises how far this area of permanent low temperature, producing a permanent anticyclonic condition at an altitude of from 5000 to 10,000 feet, may not be responsible for the existence of the low-pressure area south-east of Greenland, which exercises so large an influence on the climate of north-western Europe. The influence of the constant down-draught carrying air from

high regions of the atmosphere to sea-level has probably not been hitherto sufficiently considered by meteorologists, and the observations in Greenland suggest what the condition of things on the Antarctic ice-sheet must be. Föhn effects of a very remarkable kind were observed by Peary giving rise on one occasion to deluges of rain, which were instantly afterwards converted into solid ice.

HUGH ROBERT MILL.

MODERN MYCOLOGICAL METHODS

Mykologische Untersuchungen aus den Tropen (Mycological Researches in the Tropics) By Dr Carl Holtermann. Pp viii + 122, and Plates (Berlin: Gebrüder Borntraeger, 1898).

THE exceedingly important and original investigations prosecuted during a sojourn of fourteen months in Ceylon, Java, Borneo, and the Straits Settlements, by Dr Holtermann, can only be compared with the admirable work done by Dr Moller in Brazil, inasmuch as both authors adopted the Brefeldian method of research by means of pure cultures, and both paid special attention to the simpler forms belonging respectively to the Ascomycetes and the Basidiomycetes. Dr Holtermann commences by creating a new genus belonging to the Hemiasci, and utilises it as a means of perpetuating for all time the full name of the talented author of "Unters aus dem Gesamm der Mykologie" by calling it *Oscarbrefeldia*.

Failing a terse generic diagnosis, the salient features of the genus cannot be ascertained morphologically. The species is *O. pellucida*, bearing remarkably large conidia. The asci are terminal or rarely intercalary, and at maturity contain four 1-septate spores. A second new genus appertaining to the Hemiasci is *Comidiasus*, which, like the preceding, occurs in "Schleimfluss" on trunks of trees in company with various Anguillidæ, Bacteria, Oidium, &c. The feature of this species is that the apparent asci are in reality conidia, the protoplasm of which becomes differentiated into spores, if a structure develops, the protoplasm of which remains unsegmented, it has been considered as a conidium, if the contents divide into several bodies, each capable of germination, it has been considered as an ascus containing spores; in the present species the two are considered as conidia exhibiting a difference of degree only as to division, or not, of the protoplasm. Coming to the Basidiomycetes, we find a new species of *Lentinus* described as *L. variabilis*. Under certain conditions of culture the germinating spores produced a fertile structure resembling the genus *Hypochnus*, considered as a very primitive type of the Basidiomycetes. Under a different set of conditions, spores of the same *Lentinus* gave origin to structures resembling *Clavaria*, a type much higher than *Hypochnus*. Hence the author says—

"Hier liegt ein Fall vor, der sich mit einigem Recht zu phylogenetischen Speculationen verwenden lässt. Den der Pilz durchläuft Entwicklungsstadien, die selbständigen Formen in der freien Natur entsprechen. Das erste Stadium findet in *Hypochnus*, das andere in *Clavaria* fast einen Doppelgänger."

It has been known for a long time that species of *Lentinus*, when developing on wood in dark places, as

pits, cellars, &c., assumes very grotesque forms in which the pileus is suppressed, and the stems consequently more or less resemble species of *Clavaria*, but hitherto every one considered these productions simply as monstrosities due to an exceptional environment. Whether these antiquated views, or the later one propounded by Dr Holtermann prove to be correct, we consider yet remains to be proved.

Polyporus polymorphous, as found in nature, resembles a bracket in form attached by one edge to the matrix, from which it projects at right angles. The spores of this species in cultures produce a thin crust attached by its entire under surface to the substratum, its upper surface being covered with pores bearing the hymenium, a *Porus* in fact. In this case again, systematists have long known that the higher forms included under *Polyporus*, *Fomes*, and *Polystictus*, not unfrequently develop the resupinate or *Porus* form, often showing every transition from one to the other, but this was included under the presumed elasticity of the species, as such forms are developed more especially when the fungus occurs in conditions different from those under which it appears in its normal or highest known stage of development. Every departure from the normal form of a species cannot surely be considered as a retrogression towards a phase lower in the evolution of the species, even if the exceptional development bears a resemblance to some genus lower in the scale of organisation, and through which phase the species under consideration may presumably be supposed to have passed. Pure cultures in various nutritive media grown on a slip of glass come under the category of things grown under conditions that may be termed as exceptional, to say the least, and the fact that such developments represent phases in the normal life-history of the species investigated, or indicate its phylogeny, has yet to be proved.

Another new genus is named *Van Romburghia*, the one species stands as *V. R. silvestris*.

In the introduction the author states that as his principal object is to elucidate the life-history of forms, he has not attempted pedantic diagnoses of forms. Having been sufficiently pedantic to establish five new genera, and above a score of new species, the amount of pedantry would not have been much accentuated by the addition of diagnoses of each of these. Apart from interpretations bearing on the cultures, every mycologist will welcome the work done by Dr Holtermann, which is a model of exactness, and bears on its face the stamp of accuracy. The twelve plates add much to the value of the work.

G MASSEE.

rather one of form than substance ought, we think, to have been pointed out. Reluctance and permeability are defined and shortly treated, and tables of magnetic force, induction, and permeability are given for various kinds of iron. Then follow specimens of elementary calculations regarding magnetic circuits.

The next chapter is entitled Magneto-motive Force of Current. The magnetic fields of different simple arrangements of conductors are first discussed, thus the force at the centre of a circular coil is worked out, and the field intensity—Biot and Savart's result—for a straight current is calculated from the simple law of magnetic force due to an element of a current. This law, as a matter of fact, was derived by Laplace from Biot and Savart's result for a straight current, and the recovery of the experimental result is interesting only as showing how the inverse square of the distance law for an element leads to the law of the inverse distance for a long straight conductor. The exact directions of the magnetic forces produced by the currents in elements of conductors seem not to be always quite clearly given, and some amplification of this part of the book seems desirable. We may say that we do not like the name "mags" any more than we liked the names "hens" and "millhens," which were once proposed for other units. Abbreviations which have any flavour of etymological association should not be tolerated.

We come next to Tractive Force of Magnets and Current Reactions, with the peremeter method of testing iron, and some results thereby obtained for Krupp steel and Lowmoor iron.

Next we have a rapid account of the Generation of Electromotive Force by variation of magnetic flux through a circuit, or across a moving conductor, and the idea of self-induction is introduced. What exactly the self-induction or self-inductance of a coil is does not seem to be defined, though several things have their definitions given which certainly do not more deserve attention.

Alternators and other forms of direct current generator are described, and specimens of various calculations given. But we have looked in vain for the characteristic curves by which Hopkinson did so much for the practical working out of the dynamo. Surely in a book the object of which is to deal with practical calculations regarding magnetic circuits, this matter of all others ought to have received attention. Yet it is not even mentioned!

The book will be found to give information of considerable service on many points, but it is not homogeneous and consistent enough in its treatment. The chances are about even that if it is consulted on some important point the matter will not be found treated. With some rewriting and additions its usefulness will be much increased.

Biomechanik erschlossen aus dem Principe der Organogenese. By Dr E. Mehnert. Pp viii + 177 (Jena: Fischer, 1898).

AT a time when "vitalism" is rife, and the disbelief in Natural Selection is almost a disease, an attempt to explain the phenomena of development on mechanical grounds is very welcome.

In this treatise Mehnert has examined very thoroughly the groundwork of organogeny, and has had little difficulty in showing, by reference to the development of such organs as the heart and blood-vessels, the pineal eye, the neurenteric canal, and so on, that the exceedingly loose interpretation commonly given to the law of recapitulation, namely that embryogeny is, *pure and simple*, a repetition of phylogeny, is absolutely incorrect; in fact, the ontogenetic is frequently the very reverse of the phylogenetic order—in all cases the order of development has become changed.

By a careful consideration of very numerous facts Mehnert shows that the principal factors in this alter-

OUR BOOK SHELF.

Applied Magnetism. an Introduction to the Design of Electromagnetic Apparatus. By J. A. Kingdon, B.A. Pp 292 (London: H. Alabaster, Gatehouse, and Co.) MR. KINGDON commences his book with the magnetic flux, and his readers are evidently expected to bring their equipment of dynamics, elementary information as to units and electrical phenomena, with them. Ohm's law is introduced apparently for the purpose of bringing in its magnetic equivalent, and the fact that the coincidence is

ation have been on the one hand Abbreviation, or the early arrest of development, and Retardation, or the late appearance of the first signs of an organ, acting, together or separately, on regressive organs, while on the other hand Acceleration, or the early appearance and rapid development of an organ, and Prolongation, or gradual increase in the length of life, are influences to which progressive organs are subject.

These four factors then, separately or combined, condition ontogeny, and hence is formulated the "fundamental law of organogeny," that the rate of development of an organ is proportional to the degree, at the time, of its phyletic development, so that ontogeny is a very much modified recapitulation of phylogeny.

In the development of an individual it is therefore possible to discern two influences at work (1) the hereditary, recapitulating, phylogenetic influence, and (2) functional epigenesis, due to the direct action of inner and outer causes, such as surrounding organs, food, temperature, gravity, and so on. Mehnert is, perhaps, not as clear as he might be, when he comes to deal with the exact way in which these environmental changes have become inherited, but (without mentioning Natural Selection) he seems to tend towards a Lamarckian inheritance of acquired characters. He discards, however, a chemical pangensis, and explains the influence of the soma on the germ by a physical theory—analogueous to magnetisation—which has at least the merit of being novel.

At the end of the book are some remarks on the specific variations in embryogeny, and in length of life, and on involution.

The epigenetic modifications of the phylogenetic order, perhaps the most valuable part of this work, are graphically illustrated by numerous diagrams.

Practical Plant Physiology. By Dr. W. Detmer. Translated from the second German edition by S. A. Moor, M.A. (Camb.), F.L.S. (London: Sonnenschein and Co., Ltd., 1898).

A TRANSLATION of Detmer's "Pflanzenphysiologische Practicum" will doubtless be very acceptable to students of vegetable physiology in English-speaking countries. Since its publication Detmer's work has always been a standard one, and its second edition was in many ways a great improvement on the first. However, notwithstanding the high reputation of the German edition, it seems a pity that the translator should decide that "no sufficient reason has been found for addition or alteration", for, with but little extra trouble, a very complete English text-book could have been made of the translation. By including physiological work published since 1895, and by the addition of more complete references to older researches, the usefulness of the book would have been largely increased.

The German edition has already been reviewed in a previous number of NATURE, so that little need be said of the translation. The translator's style is good, and he reproduces faithfully the sketchy and note-book-like form of the original. It may be added that the English edition is well printed, and the illustrations have hardly suffered in their reproduction. H. H. D.

A Chemical Laboratory Course. By A. F. Hogg, M.A., F.C.S. Pp. 24. (Darlington: James Dodds, 1898.)

A SERIES of experiments, arranged to illustrate elementary chemical analysis, are briefly described in this pamphlet. The experiments are arranged to accompany lectures on water, air, combustion, &c., and they form a course of work for the elementary and advanced stages of inorganic chemistry of the Department of Science and Art. Little information is given in addition to instructions for carrying out the experiments.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

Stereo-chemistry and Vitalism

BEFORE commenting on the argument for Vitalism urged in the opening address of Prof. Japp to the Chemical Section of the British Association, it will be best to quote from the report published in NATURE such passages as clearly present his position.

He said—
"Pasteur's point is, that whereas living nature can make a single optically active compound, these laboratory reactions, to which we resort in synthesising such compounds, always produce, simultaneously, at least two, of equal and opposite optical activity; the result being intermolecular compensation and consequent optical inactivity."

"If these conclusions are correct, as I believe they are, then the absolute origin of the compounds of one-sided asymmetry to be found in the living world is a mystery as profound as the absolute origin of life itself. The two phenomena are intimately connected for, as we have seen, these symmetric (? asymmetric) compounds make their appearance with life, and are inseparable from it."

"How, for example, could levo-rotatory protein (or whatever the first asymmetric compound may have been) be spontaneously generated in a world of symmetric matter and of forces which are either symmetric or, if asymmetric, are asymmetric in two opposite senses? What mechanism could account for such selective production? Or if, on the other hand, we suppose that dextro and levo-protein were simultaneously formed, what conditions of environment existing in such a world could account for the survival of the one form and the disappearance of the other?"

The last sentence implies the assumption that in the absence of some special unknown cause, the mixed right-handed and left-handed molecules which neutralise each other's optical activities would remain mixed. But is this a valid assumption? Is there not, contrariwise, a general cause for the separation of them? Prof. Japp appears to have taken no account of a universal law displayed throughout that continuous redistribution of matter and motion which constitutes Evolution. In the second part of "First Principles" will be found a chapter entitled "Segregation," in which this law and its results are set forth. After illustrations of the process of segregation as it everywhere goes on in astronomic changes, geologic changes, changes in organisms considered individually and as an aggregate, changes throughout mental evolution and social evolution, there come at the close of the chapter the following paragraphs—

"The abstract propositions involved are these—First, that like units, subject to a uniform force capable of producing motion in them, will be moved to like degrees in the same direction. Second, that like units if exposed to unlike forces capable of producing motion in them, will be differently moved—moved either in different directions or to different degrees in the same direction. Third, that unlike units, if acted on by a uniform force capable of producing motion in them, will be differently moved—moved either in different directions or to different degrees in the same direction."

A subsequent paragraph argues that by resolution of forces it is demonstrable that any difference between the acting forces, or between the units on which they act, implies the presence of some force, active or reactive, in the one not present in the other; and that supposing the conditions are such as to permit motion, this differential force must, in virtue of the law of the persistence of force (conservation of energy) produce a differential motion. Hence the corollary is that—

"Any unlikeness in the incident forces, where the things acted on are alike, must generate a difference between the effects; since otherwise, the differential force produces no effect, and force is not persistent. Any unlikeness in the things acted on, where the incident forces are alike, must generate a difference between the effects; since otherwise, the differential force whereby these things are made unlike, produces no effect, and force is not persistent."

I This passage was written in 1866 at a time when the nomenclature now current was not established. Hence the use of the word persistence, for the energy. I still, however, adhere to the use of the word persistence, for the

Now from this process of segregation it must have happened that when "dextro- and levo-protein were simultaneously formed" the two kinds of molecules, differently related to environing actions (say ethereal undulations alike in nature and direction), separated themselves into groups of their respective kinds. It is true that in virtue of the small differences between the two classes of molecules, the minute differential actions of forces upon them might be long in producing their effects, and, further, that the segregation might be impeded by restraining forces. But when we remember that segregations take place in long periods of time even where the restraining forces are very great, as instance the formation of hematite nodules and flints in chalk-formations or of siliceous concretions in limestone, the implication is that the segregation would slowly, if not quickly, take place. And then the molecules of either group would exhibit just that optical activity which Prof Japp, following Pasteur, alleges can result only from molecules formed by vital action.

I do not draw attention to this truth for the purpose of showing the adequacy of the physico-chemical interpretation of life, but for the purpose of showing the inadequacy of Prof Japp's argument against it. My own belief is that neither interpretation is adequate. A recently-issued revised and enlarged edition of the first volume of the "Principles of Biology" contains a chapter on "The Dynamical Element in Life," in which I have contended that the theory of a vital principle fails and that the physico-chemical theory also fails. The corollary being that in its ultimate nature life is incomprehensible.

Brighton, October 12. HERBERT SPENCER

Organic Variations and their Interpretation

I SHOULD like, if you will kindly afford me a little space, to offer a few remarks on Prof Weldon's presidential address to Section D of the British Association.

The first part of that address deals with the question whether individual variations are fortuitous or occur by chance. It contains a very able and lucid exposition of the fact that the distribution of individual variations is of a similar kind, and is open to the same mathematical treatment, as events which happen by chance. I do not think that any one has denied this. It does not admit of dispute. But it is no answer whatever to the reasoning of those who oppose the theory of Natural Selection. The question is whether a given modification, the degree of which is distributed among individuals according to what may be called the law of chance, originated accidentally, or as the result of a definite ascertainable cause. To give an illustration. If I plant a hundred or a thousand sunflower seeds in good soil in a market garden, at about equal distances from one another, I get a number of sunflower plants which will not all be of the same size. If I measure their heights, or take their weights, I shall find that these magnitudes are so distributed as to form one of Prof Weldon's curves. If I take another hundred or thousand seeds from the same sack, and plant them in flower-pots, each 6 inches in diameter and of exactly the same capacity, placing the flower-pots in the same garden, I shall get a number of sunflower plants whose heights or weights will form a curve of the same kind. But the mean height or weight of the second lot of plants will be very much less than that of the first lot. This I know to be true because I have tried it. The distribution of the magnitudes has nothing whatever to do with the cause of the difference in the two cases. That cause is limited nourishment in the second case. Similarly in the progressive modification of animals and plants under natural conditions, the distribution among individuals of the degrees of a character has nothing whatever to do with the question of the cause of the character. When selection takes place, by breeding from the larger or the smaller variations, the mean of a character may be raised or lowered, but the question is whether this can be done without regard to conditions of life or not. In numbers of cases there is reason to believe that it cannot. And there is reason to believe that in numbers of cases the mean of a character can be raised or lowered by the application of definite conditions without any selective breeding at all. I will not attempt to prove this here; all I wish to reason that the word conservation is doubly inappropriate. Conservation connotes a conserving and an act of conserving—conceptions utterly at variance with the doctrine asserted, and it also implies that in the absence of a conserving and an act of conserving, the word disappear, which is also a conception utterly at variance with the doctrine asserted.

point out is, that Prof Weldon's argument does not touch the question.

Still more serious objections must be made to Prof Weldon's evidence concerning the actual operation of selection with regard to the frontal breadth of *Carcinus maenas*. I do not dispute his measurements, but his interpretation of them, which seems to me obviously and demonstrably unsound. He finds that the mean frontal breadth of the crabs at Plymouth was less in 1895 than in 1893, and less in 1898 than in 1895. I have always held that he courted failure by taking for investigation a character which is known to be undergoing progressive change in the individual during growth. We know that change in the proportions of a crab occur only at the ecdysis. It is, I think, certain that the number of ecdyses depend on age, not on size. Prof Weldon himself remarks that the estimate of age by size is a dangerous proceeding. Yet for individual variations he compares crabs of the same size, not of the same age. Now the results he finds with regard to the diminution in frontal breadth in terms of total length would be exactly the same, if the growth of the crabs had been less in 1895 and 1898 than in 1893, in other words, if the crabs of the same size had been in these years, on the average older, had on the average passed through more moults; for the older crab has a relatively smaller frontal breadth. Now have I any reason for supposing that the crabs grew more rapidly in 1893, and do I suppose that the increased muddiness of the water in Plymouth sound caused a diminution in the rate of growth? I do not suppose that mud had anything to do with it, but I have good reason for holding that crabs, like oysters, grow faster and larger when the water is warmer. Here is what Mr Garstang writes in 1894 concerning the summer of 1893. "Under the influence of the great heat the temperature of the Channel waters rose continuously, until in August it attained a point unprecedented for a quarter of a century, and it was of the highest interest to observe the effect of this high temperature, and of the prolonged calmness of the sea, upon the floating population of the neighbouring portions of the Channel. Numbers of semi-palmate forms, which rarely reach our shores arrived in remarkable profusion. In June the tow nets were crowded with Salps, while towards the latter end of August they were almost choked by masses of living *Radialia*." The beginning of the year 1895, on the other hand, was exceedingly cold, and in the summer the water temperature was less than in 1893. It is not certain, as so few crabs were measured in 1898, whether their mean frontal breadth was really less than in 1895. But it is a fact that although last winter was unusually mild, the water temperature off Looe in May and June was lower than in the same months in 1895.

It is remarkable that Prof Weldon found the change in female crabs was less than in males, and it is difficult to understand why the sexes should be affected in different degrees by an increase in the muddiness of the water. On the other hand, as the males in crabs generally are larger than the females, the former would necessarily be more affected in their growth by temperature.

Next as to the experiment which is adduced to show that the increase of sediment is the cause of the selective destruction of the crabs with greater frontal breadth. The survivors of crabs placed in water with china clay had narrower foreheads. But this merely means that they were on the average older, and the younger specimens were killed first, which is what might be expected. Prof Weldon believes that the cause of death was the entrance of the sediment into the gill chamber, but it appears that the dead crabs had been in the muddy water, while the living were killed after removal. There is no evidence that the clay entered before death, and any dead crab which had been some time in muddy water constantly stirred would probably have mud on its gills.

Lastly there is the experiment of keeping crabs in bottles for a period including a single moult. At first the crabs with broader foreheads died, and in this case the death is attributed to the putridity of the water. In this case there was no sediment, and putrefaction in the water has the same effect as sediment, a fact perfectly in agreement with the view that under unfavourable conditions the younger die first, but inconsonant with the view that death is due to the greater filtering power of the branchial apparatus in the narrower fronted crabs. The mean frontal breadth having been decreased by selective deaths before the moult, was found, after the moult, to be greater than that of crabs from the sea of the same size. This again is easily explained by increased growth. The crabs in the bottles were

in warmer water and better fed than those in the sea, and therefore on the average were younger after the moult than a number from the sea of the same size. In fact the diminution of frontal breadth depends not on the size of the crab, but on the number of moults it has passed through, while the size depends on the increase at each moult. A crab which has moulted seven or six times may be smaller than one which has only moulted five or four times.

Another case is on record which seems to me to afford an exact parallel to Prof. Weldon's. In Darwin's "Descent of Man" is quoted the evidence of a hunter who asserted that in a certain district male deer with a single unbranched antler were becoming gradually more numerous and taking the place of those with normal branched antlers. The district referred to was that of the Adirondack Hills in North America. As the witness in question had hunted deer for twenty-one years, Darwin considered his evidence important. J. D. Caton, however, who for many years made the Cervidae his special study in Canada, particularly investigated this case. He satisfied himself that there was no truth whatever in the evidence above mentioned. *The spike horn bucks seen and killed in the Adirondacks were all yearling bucks with their first antlers.* In all species of Cervus the horns which first grow are simple pointed unbranched spikes; and to prove the existence of spike-horned bucks as a variety, it would be necessary to show that when they cast their horns they developed simple spikes every year throughout life. No attempt was made to prove this, and Caton describes cases which he observed himself, in which spike horned bucks of unusually large size, which might have been supposed to be full grown, developed branched horns in the following year.

A final objection to Prof. Weldon's argument may be mentioned. All the crabs on whose measurements he bases the conclusion that the relative frontal breadth of the species in Plymouth Sound has actually decreased within a few years, are small specimens to 15 mm., or about half an inch in length of carapace. He makes no attempt to show that the decrease has occurred in adult crabs. The efficiency of filtration would necessarily depend on the absolute size of the filtering mechanism, not on the relative size, since the size of the particles of mud to be excluded remains the same. A crab therefore which survived in consequence of its narrow frontal region at the size of half an inch, would have no advantage when it was 2 or 3 inches long, as the frontal region would then be absolutely much greater. If the mud then kills the small crabs with a broad frontal region, it ought to kill all the adult crabs without exception.

A simple method of testing the soundness of Prof. Weldon's conclusion, with regard to the crabs in Plymouth Sound, would be to compare the mean frontal breadth of adult crabs from that locality, with that of others collected outside the Sound, e.g. at the mouth of the Yeslim, where the water is pure, and at Salsburgh, where the water is much more turbid. If the sediment in the Sound is really decreasing the mean frontal breadth by a process of selection, that dimension must be greater in clean water, and less where there is still more sediment. J. T. CUNNINGHAM

Penzance, September 24

I SHOULD like to be allowed to make a few remarks upon Prof. Weldon's address to the Zoological Section of the British Association; for it seems to me—very interesting as it is—that it is entirely outside the real question of the evolution of varieties and species of animals.

My contention is that individual differences—within which Prof. Weldon is solely concerned—do not afford the materials for new varieties or species (I would refer the reader to my paper on "Individual Variations," *Natural Science*, vol. vi, p. 385).

A systematist has to consider differences of "form" as well as, and indeed, he regards it as much more important than, "size" or "number." Prof. Weldon, however, refers only to size in crabs and recruits, and to number in pigs' glands and petals of the buttercup.

If I understand Darwin's theory of "The origin of species by means of natural selection," an individual has some slight variation or new feature, which is beneficial to it in the struggle for life among other organisms, more especially of the same kind—as a "large population" of the same sort is what Darwin and Dr. Wallace demand—then, such an individual may prove itself best fitted to survive and ultimately establish a new variety, the others dying out in the struggle.

But, for one or more crabs to have a frontal breadth a little less than that of others in a group of the same kind of crab is no new feature. It is only an "individual difference," such as all organisms are subject to.

"Number" and "size," to be included in varietal characters must be more pronounced than in the case with the crabs. The extreme lengths of the carapace are given as 10 to 1 and 14.9 millimetres—i.e. two-fifths and three-fifths of an inch; but between those killed by suffocation and the smaller survivors, the greatest difference lies between 816 17 and 987 36, these numbers being the highest "mean frontal breadths in terms of carapace length = 1000", so that the difference is 28 81, not 3 per cent.

Upon such insignificant differences the life or death of the crabs is supposed to hang!

But the contention presumably is that the smaller crabs will form a new variety. Will any zoological systematist accept this?

But is it not obvious that if natural selection has been always constantly at work in this supposed way with individual differences among plants and animals, some varieties might be looked for among buttercups and *Carusius menas*? Take *Ranunculus Ficaria*, which furnished Mr. Burkill with materials for like observations (*NATURE*, February 7, p. 359, 1895), the petals of which vary much more in number than do those of buttercups. If natural selection has been busy over this species for centuries, how is it that it remains *R. Ficaria* still? It grows in all sorts of places, favourable and unfavourable. It would be easy to make curves for individual differences for the number of petals, stamens, size of leaves, tubercles, &c., but it would all be a waste of energy as far as advancing any illustrations of evolution. Individual differences come up every year, in spite of natural selection and all its imaginary doings. Moreover similar individual differences occur in the leaves all over one and the same tree and of every kind, what can natural selection do among them?

In fact, no one has ever yet shown that a new species has ever arisen out of individual differences "observed in the individuals of the same species inhabiting the same confined area" ("Origin of Species," 6th ed., p. 34).

The utmost that Prof. Weldon has shown is that, under abnormal and dangerous circumstances, which have killed off other kinds of marine animals from the Sound at Plymouth, crabs are dying out too; but that the larger ones (older?) are killed off more slowly, perhaps, than the younger. Is this due to the gills a little larger, so as to allow an easier passage for the mud? We may compare this with the London fogs in winter, which raise the death rate of older members of the community.

Prof. Weldon says: "I will show you that in those crabs small changes in size of the frontal breadth do, under certain circumstances, affect the death-rate."

As this is the very kernel of the whole matter—for he quotes Darwin as saying, "the theory asserts the smallest observable variation" (observe Darwin requires a "variation," but there is none at all in any of Prof. Weldon's four examples)—may affect an animal's chance of survival, one anxiously looked out, on reading the address through, for the fulfilment of this promise, but near the end, all he says is, that the immediate cause of death was suffocation by mud clogging the gills, and adds "I think it can be shown that a narrow frontal breadth renders one part of the process of filtration of water more efficient; that is in crabs of greater frontal breadth."

This opinion is unfortunately no scientific proof; and it is much to be regretted that he did not give us the grounds for his so thinking.

He only measured the carapaces and frontal breadths, but it is presumable that the legs were proportionally longer in the deceased crabs. The question therefore arises, were they, too, concerned in causing the increased death-rate of those with the bigger carapaces?

Of course, who has all this got to do with evolution? No one will dispute these interesting illustrations of chance—a name for all cases where one cannot trace actual causes, or inductive evidence—and its application to individual differences; which, by the way, Dr. Wallace now regards as "non-specific or developmental characters" (*Fortnightly Review*, March 1895, p. 444), and not leading to new varieties; as he did in his work on "Natural Selection" in 1871.

Natural selection determines what shall survive and what shall die in the universal struggle for life; but it has yet to be shown, that the origin of species has anything to do with it.

Prof. Weldon concludes with the observation that "numerical knowledge of this kind is the only ultimate test of the theory of natural selection, or of any other theory of any natural process whatever."

It has tested natural selection, and shown that nothing of the nature of a *true variety* has been established by it. There is no *evolution* in the process described at all.

Does he not speak a little too confidently as to there being no other means of investigation into the procedure of evolution?

The true method of establishing this doctrine, as in all other matters of science, I take to be by *inductive evidence and experimental verification*. By these it has been proved that true varietal changes are produced by what Darwin called "the definite action of changed conditions of life," and he added that when this was the case "a new sub variety would be produced without the aid of natural selection" ("Animals and Plants under Domestication," vol. i, pp. 271, 272).

In support of this contention of Darwin's I shall be happy to supply Prof. Weldon with an abundance of facts collected in my book, "The Origin of Plant Structures," if he will promise to read it, entirely unbiased by his established belief in the efficacy of natural selection. GEORGE HENSLON
So Holand Park, W

THE points raised by Mr. Cunningham are numerous, and I trust that he will not think me wanting in courtesy if I make my answer to each of them as short as possible.

(1) I am glad Mr. Cunningham now believes that the fortuitous character of animal variation is in many cases indisputable, so that he no longer holds the view of chance adopted by Eimer and others (i. e., "Organic Evolution," translated by J. T. Cunningham Macmillan, 1890).

(2) I cannot agree that the question, which the theory of natural selection attempts to answer, is the question "whether a given modification . . . originated accidentally, or as the result of a definite ascertainable cause." Without discussing the conception of an "action" implied in this phrase, I fail to see that the theory of natural selection involves a theory of the origin of variation. All it asserts is that the variation which is known to occur does affect the death-rate.

(3) The well-known fact, that a change in surrounding conditions often produces a change in the character of a race by methods other than that of selective destruction, does not disprove the co-existence of selective destruction. For example, Mr. Cunningham has not shown that the adaptation of sunflowers to life in six-inch flower-pots is effected without selective destruction. He has only shown that a portion of the change, associated with life in pots is effected without such destruction. By dividing a sample of seed of known origin into two portions, sowing seeds of one portion in a market garden, seeds of the other portion singly in a series of flower-pots, Mr. Cunningham has produced two different series of sunflowers, which differ in stature and in other characters. I fully accept Mr. Cunningham's statement that the plants in the flower-pots were modified without selective destruction. But these plants were not all alike, and unless it can be shown that each of them produced an equal number of seeds, of equal germinating power, so that if life in flower-pots had been continued each plant, whatever its stature, would have contributed an equal number of equally fertile offspring to the next generation, — unless this can be shown, the action of natural selection is by no means disproved. If among the sunflowers of different stature growing in similarly flower-pots, plants of one stature produced more seed than plants of different stature, the plants of that stature were better "adapted" to life in flower-pots than the others, and in a struggle to occupy a world filled with six-inch flower-pots, the offspring of the more fertile plants would very probably win; so that a process of natural selection would occur. So far as Mr. Cunningham has described his observations, they do not exclude the possibility that this and other kinds of selection operate. All I am anxious to know, in those cases of organic evolution which I try to understand, is how much of the observed change is due to a process of selective destruction, how much to other causes.

(4) I heartily agree with the view that it is not possible for selection, under fixed conditions, to modify a species in every direction. It is only possible for natural selection to act so as to produce a race with a minimum death-rate. For example, since muddy water of a certain salinity kills broad-fronted crabs more quickly than narrow-fronted crabs, it is probably im-

possible for natural selection to increase the frontal breadth of crabs which live in such water.

(5) In the second part of his letter, Mr. Cunningham attempts an explanation of the evolution observed in Plymouth crabs, which does not involve any selective destruction. For this purpose he makes two hypotheses, one about the growth of crabs, one about the temperature of the sea shore at Plymouth. Neither of these hypotheses seems to me to fit the facts. If I understand the hypothesis about growth, it is this: that the frontal breadth of a crab depends on its age, while the length of a crab depends not only upon age, but upon temperature and other circumstances affecting it during growth. From this it is deduced that in a group of crabs of the same length, those with narrower fronts are older, those with broader fronts are younger, and I suppose that those with equal fronts are assumed to be of the same age. Therefore, when I say that under certain conditions the crabs with the broadest fronts die first, Mr. Cunningham assumes that under those conditions the youngest crabs die first. I do not know of any published account of the growth of crabs which supports this hypothesis, and the following facts seem to disprove it. — If we take a group of crabs, of the same length and the same frontal breadth, they are, on this view, nearly of an age. If we keep these crabs till they moult, they will grow at different rates during the moult; now those which increase abnormally much in length during the moult, will be younger than average crabs of their new length, those which show abnormally little increase in length, will be older than the majority of crabs of their new length. Mr. Cunningham says that in crabs of a given length, the youngest are the broadest, therefore those crabs which grew abnormally much ought to have broader fronts than their fellows of their new length, those crabs which grew abnormally little ought to be narrower than their fellows. I have worked out the relation between growth-rate and frontal breadth abnormality in more than 500 cases, and the relation which ought to hold, if Mr. Cunningham's hypothesis were true, does not hold.

The further disproof of the contention that the youngest crabs died first in my experiments is this. — In most of the experiments about equal numbers of crabs of all lengths from 10 to 15 mm. were treated together; and all crabs used in an experiment were gathered on one day. It will hardly be contended that irregularity of growth goes so far as to produce in the same season crabs between 10 and 11 mm. long which are of the same age as crabs between 14 and 15 mm. long. If the younger crabs died first in my experiments, a mortality of 70 or 80 per cent. might be expected to kill all, or nearly all the shorter crabs, the survivors being derived almost entirely from the longer crabs. This was not the case. For example, in one experiment 200 crabs, between 10 and 15 mm. long, were treated with mud until only four were left alive. These four were respectively 10.67 mm., 11.67 mm., 11.43 mm., and 12.11 mm. long.

(6) Mr. Cunningham further supposes, and no doubt rightly, that crabs grow faster, within certain limits, the warmer the water in which they are; so that crabs 10 mm. long, grown in warm water, are probably younger than crabs 10 mm. long, grown in colder water. From observations made on the temperature of the Channel water, he thinks it probable that the crabs measured in 1893 were on the whole younger than those measured in 1895, and those measured this year were oldest of all, — all the crabs being of the same length. The reason for this is that the water in the Channel was exceptionally hot in 1893, and for some time exceptionally cool this year. But the stony beach where these crabs were collected looks due south, and is uncovered for hours daily, when it is often exposed to the direct rays of the sun. I am most unwilling to believe that the temperature on such a beach was lower during the past summer than in 1893. A further point is that crabs gathered in January ought, if Mr. Cunningham's hypothesis were true, to be distinctly narrower than crabs of the same length gathered in August. Crabs gathered last January were narrower than crabs gathered in August 1893, but they were not narrower than crabs gathered last August. So that all Mr. Cunningham's ingenious hypotheses fail to fit the facts.

(7) Mr. Cunningham says that there is no evidence of the entrance of fine mud into the gill chambers of crabs during life. If he will watch a crab breathing in muddy water, or if he will consult the works of Mr. Garstang and other students of the subject, he will see that he is mistaken. I thought the entrance of such particles into the gill chamber so well known that I need

not describe experiments (of which I have made plenty) in proof of its occurrence.

(8) I quite agree with Mr. Cunningham and Mr. Henslow, that it is my duty to describe the effect I believe fine mud to have upon the respiratory apparatus, and I am preparing such a description as quickly as I can. I hope also to be able before long to answer Mr. Cunningham's last and very pertinent question, whether crabs of given length, from the clear water outside Plymouth Sound, are broader or narrower than crabs of the same length from muddy waters within the Sound.

(9) I altogether fail to understand Mr. Henslow's letter, and I fear that my imperfect exposition has led him to misunderstand me as completely as he has misinterpreted one of the clearest passages in the "Origin of Species." Mr. Henslow suggests that a variation, fit to afford material for natural selection, must be a *new* character, differing in some mysterious and undefined way from those individual differences which he refuses to call variations, and he further attributes the same view to Mr. Darwin. If Mr. Henslow will read once more the section of the fourth chapter of the "Origin of Species" headed "Illustrations of the Action of Natural Selection, &c.," he will see that Mr. Darwin does not express this opinion. The important thing to determine is not what any man, however eminent, has said about the importance of differences between individual animals, but what that importance can be shown to be. The crabs at Plymouth have not, during the past five years, exhibited any changes in the magnitude of their frontal breadth which Mr. Henslow would rank as a variation, but they have exhibited individual differences. During these five years the mean frontal breadth ratio has changed nearly 2 per cent., so that the change now going on would produce, if it were to continue at the same rate for fifty years, a change big enough to constitute a difference which most men would rank as specific. I have endeavoured to show that this change has been accompanied by a destruction which has acted selectively upon individual differences. Mr. Henslow has not seriously discussed this attempt of mine, but ridicules the idea that so small a change can be of importance in relation to evolution. If the mean stature of Englishmen were to diminish by an inch in a few years, I presume Mr. Henslow would regard such change as rapid and important; but the percentage change would be less than that which Mr. Thompson and I have demonstrated during the past five years in crabs.

Mirage on City Pavements

DURING my summer visits to San Francisco, I have been so frequently struck with the beautiful miniature mirages that can be seen on the flagstone sidewalks whenever the sun shines, that I determined to secure, if possible, a photograph of the phenomenon on a scale suitable for reproduction. One or two

previous attempts in past years having been partial failures owing to the smallness of the image, I secured, through the kindness of a friend, the use of a very fine tele objective capable of giving an image six or eight times as large as an ordinary objective of 12 inches focus. The streets over some of the hills are so laid out that it is possible, on nearing the brow, to bring the eye on the level of the side-walk, and look along a perfectly level stretch of one hundred yards or more. Standing in this position it is almost impossible to resist the conviction that the

walk is flooded with a perfectly smooth sheet of water, in which the reflections of pedestrians can be seen as distinctly as in a mirror.

In order to observe the phenomenon it is necessary that a considerable stretch of level pavement be foreshortened into a very narrow strip. This is the condition in the photograph: the camera stood just below the brow of the hill, and the distance in the photograph from the X to where the children and the toy cart are standing, is an entire block (135 yards). The position of the camera and section of the hill-top are shown in the diagram. The apparent reflections, due to the

bending upward of the rays by the thin layer of heated air, come out very clearly in the picture, but the camera fails to give a correct reproduction of the extreme brilliancy of the reflecting layer of air.

On taking a few steps up the hill, decreasing the foreshortening, the glaze vanishes, and we see only the dull grey of the flagstones. Extremely hot sunshine is not necessary. I have observed the phenomenon early in the morning after a cold night, before the sun had reached the pavement, the slight warmth from the ground being sufficient. Under these conditions, however, the pavement must be more foreshortened than when in the full sunshine. The refracting layer is probably only a thin skin of warm air, which adheres as it were to the surface of the flagstones, for the mirage is unaffected by the strong winds which frequently sweep the top of the hill.

Probably these mirages can be seen on any level pavement where the eye can be brought into the proper position.

Transference of Heat in Cooled Metal

My attention has just been called to two communications to your journal, entitled "Transference of Heat in Cooled Metal." The first, by M. Henry Bourget, appears in the issue of June 30, and the second, by Mr. Albert T. Bartlett, in the issue of September 1.

About the year 1880 I had occasion to heat one end of an iron bar to a bright red heat whilst holding the cooler end in my hand. Upon plunging the heated end into a bucket of water the cooler end became suddenly so hot that I was obliged to release my hold on it.

This phenomenon interested me very much, as I could find no explanation for the apparent reflection of heat to the cooler end of the bar; and in 1888, whilst working in the physical laboratory at Johns Hopkins University, I further investigated the matter.

To one end of an iron or steel bar was soldered a thermo-electric couple, the circuit of which was closed through a very sensitive, high resistance, Rowland, reflecting, galvanometer. The bar was passed through two pasteboard screens, and was supported in a horizontal position, the screens serving to intercept any heat which might be conveyed by radiation or convection through the air from one end of the bar to the other. Under the end of the bar, remote from that to which the thermo electric couple was soldered, was placed a compound bunsen burner, by which the end of the bar was raised to a dull red heat. The spot of light on the galvanometric scale

moved off to the right very gradually as the cooler end of the bar became heated, but was brought back to a convenient point on the scale by means of a controlling magnet. When the state of steady flow was reached, the burner flame was removed, and water was immediately poured over the heated end of the bar. The spot of light on the galvanometer scale immediately moved off to the right, indicating an immediate rise of temperature at the cooler end of the bar.

The rapidity of the action was a second source of surprise to me, as it far exceeded the velocity of propagation of heat along the bar by conduction. I was obliged to discontinue this line of work for a time, and did not return to it till 1895, when I repeated the experiments described above, this time, however, using brass rods of various dimensions. In the case of the brass rods I failed to observe the same phenomenon, and concluded that the effect was due, as I had supposed in 1888, to much the same cause as recalcination.

I should judge from my results that if the effect exists at all in brass, it is yet much more pronounced in iron or steel.

At the time I made my experiments at Johns Hopkins University, I drew the attention of Prof. Jerry A. Rowland and Dr. Louis Duncan to the matter, the latter witnessing the experiments, and later I discussed it with Prof. Ogden N. Rood, of Columbia University, New York City. Prof. Rowland pointed out that theoretically there should be a very slight instantaneous effect, but that it should be a reduction and not an increase of temperature.

That the effect just described is altogether unaccounted for by the present mathematical theory of the propagation of heat in conductors is not very surprising in view of the fact that that theory postulates the constancy of the specific heat and thermal conductivity of the medium, whereas at high temperatures these properties vary considerably with the temperature, and particularly in the case of iron, the physical state undergoes a complete change of what Hopkinson termed the *critical temperature*, which varies in different specimens from 690° C to 870° C.

In attempting an explanation of the phenomenon which we have been discussing, it seems to me to be fatal to assume that the heat producing the sudden rise of temperature observed, is not transmitted along the rod with the great velocity observed in the tests, but that it exists at the cooler end of the rod before the rise of temperature occurs. When iron or steel which has been heated to redness is suddenly plunged into water a marked change takes place in the properties of the metal, and if this change of character in the metal is in part transmitted from particle to particle to the other end of the rod, and results in a lowering of the heat capacity of the material, a rise of temperature will result as observed.

Animals and Poisonous Plants

FROM repeated observations in my own garden, I know that song-thrushes will eat ripe *Daphne* berries greedily. In the winter of 1896 they cleared a small bush containing, perhaps, two hundred berries, in the course of a week or two, returning at once when driven away, and becoming half-stupefied; so that they might, apparently, have been caught with the hand.

Dr. Withering states ("British Plants," ed 1812) that six berries of this shrub (*Daphne mezereum*) will kill a wolf.

According to the same authority, *Cuscuta torea* is a certain poison to cows, while goats devour it eagerly, and it is not injurious to sheep and horses. As to *Atropa belladonna*, a case which received much attention at the time may be found in the daily papers of some twenty years ago. A family were poisoned by eating rabbit-pie, the symptoms being those of atropine poisoning; and the inquiry, which followed, showed that rabbits do not eat deadly nightshade berries.

J. C.
Loughton, Essex.

WITH reference to Mr. Bennett's inquiry as to the consumption of poisonous berries by birds, I remember a young blackbird, some years back, who used to frequent the garden of the house in which I was staying, and who eagerly swallowed the berries of the *Daphne mezereum*. He was rather tame and would take them when I threw them to him, following them as they rolled along the ground, as a chicken would go after peas. I see that Sowerby confirms the ordinary opinion as to the

poisonous nature of these berries. "The whole plant is a powerful irritant, both bark, leaves and fruit acting poisonously if taken in large quantities. A few of the berries have been known to cause death when swallowed." The blackbird did not seem the worse for them.

EDWARD M. LANGLEY.
16 Adelaide Square, Bedford, October 15.

An Osteometric Index-Calculator.

I SHOULD feel obliged if any of your readers could inform me whether there is in use among anthropologists any mechanical appliance by which indices can be determined without loss of time and the possible inaccuracy attending an arithmetical calculation.

I am anxious to obtain information on this subject in order to find out if there is any simpler or possibly better instrument than one I have constructed. It consists of a graduated quadrant and a movable arm, and it is very helpful in doing the purely arithmetic work, as it shows accurately, at a glance, the index required from any two figures, and does not work by logarithms, as does the slide rule of engineers, which might be used for the purpose.

The Dene, Rottingdean, October 14.

A SHORT HISTORY OF SCIENTIFIC INSTRUCTION¹

II

I MUST come back from this excursion to call your attention to the year 1845, in which one of the germs of our College first saw the light.

What was the condition of England in 1845? Her universities had degenerated into *Austrian lycées*. With regard to the University teaching, I may state that even as late as the late fifties a senior wrangler—I had the story from himself—came to London from Cambridge expressly to walk about the streets to study crystals, prisms, and the like in the optician's windows. Of laboratories in the universities there were none, of science teaching in the schools there was none, there was no organisation for training science teachers.

If an artisan wished to improve his knowledge he had only the moribund Mechanics' Institutes to fall back upon. The nation which then was renowned for its utilisation of waste material products allowed its mental products to remain undeveloped.

There was no Minister of Instruction, no councillors with a knowledge of the national scientific needs, no organised secondary or primary instruction. We lacked then everything that Germany had equipped herself with in the matter of scientific industries.

Did this matter? Was it more than a mere abstract question of a want of perfection?

It mattered very much! From all quarters came the cry that the national industries were being undermined in consequence of the more complete application of scientific methods to those of other countries.

The chemical industries were the first to feel this, and because England was then the seat of most of the large chemical works¹.

Very few chemists were employed in these chemical works. There were in cases some so-called chemists at about bricklayers' wages—not much of an inducement to study chemistry, even if there had been practical laboratories, where it could have been properly learnt. Hence when efficient men were wanted they were got from

¹ An address delivered at the Royal College of Science by Sir Norman Lockyer, K.C.B., F.R.S., on October 6. (Continued from page 575.)

² Perkin, NATURE, xxiii, 334.

abroad—i.e. from Germany, or the richer English had to go abroad themselves.

At this time we had, fortunately for us, in England, in very high place, a German fully equipped by all that could be learned at one of the best equipped modern German Universities, where he studied both science and the fine arts. I refer to the Prince Consort. From that year to his death he was the fountain of our English educational renaissance, drawing to himself men like Playfair, Clark and De la Beche; knowing what we lacked, he threw himself into the breach. This College is one of the many things the nation owes to him. His service to his adopted country, and the value of the institutions he helped to inaugurate, are by no means even yet fully recognised, because those from whom national recognition full and ample should have come, were, and to a great extent still are, the products of the old system of middle age scholasticism which his clear vision recognised was incapable by itself of coping with the conditions of modern civilised communities.

It was in the year 1845 that the influence of the Prince Consort began to be felt. Those who know most of the conditions of Science and Art then and now, know best how beneficial that influence was in both directions, my present purpose, however, has only reference to Science.

The College of Chemistry was founded in 1845, first as a private institution; the School of Mines was established by the Government in 1851.

In the next year, in the speech from the Throne at the opening of Parliament, Her Majesty spoke as follows:—"The advancement of the Fine Arts and of practical Science will be readily recognised by you as worthy the attention of a great and enlightened nation. I have directed that a comprehensive scheme shall be laid before you having in view the promotion of these objects, towards which I invite your aid and co-operation."

Strange words these from the lips of an English sovereign.

The Government of this country was made at last to recognise the great factors of a peaceful nation's prosperity, and to reverse a policy which has been as disastrous to us as if they had insisted upon our naval needs being supplied by local effort as they were in Queen Elizabeth's time.

England has practically lost a century, one need not be a prophet to foresee that in another century's time our education and our scientific establishments will be as strongly organised by the British Government as the navy itself.

As a part of the comprehensive scheme referred to by Her Majesty, the Department of Science and Art was organised in 1853, and in the amalgamation of the College of Chemistry and the School of Mines we have the germ of our present institution.

But this was not the only science school founded by the Government. The Royal School of Naval Architecture and Marine Engineering was established by the Department at the request of the Lords Commissioners of the Admiralty "with a view of providing especially for the education of shipbuilding officers for Her Majesty's Service, and promoting the general study of the Science of Ship Building and Naval Engineering." It was not limited to persons in the Queen's Service, and it was opened on November 1, 1864. The present Royal College of Science was built for it and the College of Chemistry. In 1873 the School was transferred to the Royal Naval College, Greenwich, and this accident enabled the teaching from Jermyn Street to be transferred and proper practical instruction to be given at South Kensington. The Lords of the Admiralty expressed their entire satisfaction with the manner in which the instruction had been carried on at South Kensington; and well they might, for in a memorandum submitted to the Lord President in 1887, the President and Council of the

Institute of Naval Architects state:—"When the Department dealt with the highest class of education in Naval Architecture by assisting in founding and by carrying on the School of Naval Architecture at South Kensington, the success which attended their efforts was phenomenal, the great majority of the rising men in the profession having been educated at that Institution."

Here I again point out, both with regard to the School of Mines, the School of Naval Architecture, and the later Normal School, that it was stern need that was in question, as in Egypt in old times.

Of the early history of the College I need say nothing after the addresses of my colleagues, Profs. Judd and Roberts Austen, but I am anxious to refer to some parts of its present organisation and their effect on our national educational growth in some directions.

It was after 1870 that our institution gradually began to take its place as a Normal School—that is, that the teaching of teachers formed an important part of its organisation, because in that year the newly-established Departments having found that the great national want then was teachers of Science, began to take steps to secure them. Examinations had been inaugurated in 1859, but they were for outsiders, conferring certificates and a money reward on the most competent teachers tested in this way. These examinations were really controlled by our School, for Tyndall, Hofmann, Ramsay, Huxley, and Warrington Smyth, the first professors, were also the first examiners.

Very interesting is it to look back at that first year's work, the first cast of the new educational net. After what I have said about the condition of Chemistry and the establishment of the College of Chemistry in 1845, you will not be surprised to hear that Dr. Hofmann was the most favoured—he had forty-four students.

Prof. Huxley found one student to tackle his questions, and he failed.

Profs. Ramsay and Warrington Smyth had three each, but the two threes only made five, for both lists were headed by the name of

Judd, John W.,
Wesleyan Training College,
Westminster.

Our present Dean was caught in the first haul.

These examinations were continued till 1866, and upwards of 600 teachers obtained certificates, some of them in several subjects.

Having secured the teachers, the next thing the Department did was to utilise them. This was done in 1859 by the establishment of the Science Classes throughout the country which are, I think, the only part of our educational system which even the Germans envy us. The teaching might go on in schools, attics or cellars, there was neither age-limit nor distinction of sex or creed.

Let me insist upon the fact that from the outset practical work was encouraged by payments for apparatus, and that latterly the examinations themselves, in some of the subjects, have been practical.

The number of students under instruction in Science Classes under the department in the first year in which these classes were held, was 442; the number in 1897 was 202,496. The number of candidates examined in the first year in which local examinations were held, was 650, who worked 1000 papers, in 1897 the number was 106,185, who worked 159,724 papers, chemistry alone sending in 28,891 papers, mathematics 24,764, and physiography 16,879.

The total number of individual students under instruction in Science Classes under the Department from 1859 to 1897 inclusive has been, approximately, 2,000,000. Of these about 900,000 came forward for examination, the total number of papers worked by them being 3,195,170.

Now why have I brought these statistics before you?

Because from 1861 onwards the chief rewards of the successful students have been scholarships and exhibitions held in this College; a system adopted in the hope that in this way the number of perfectly trained Science Teachers might be increased, so that the Science Classes throughout the country might go on from strength to strength.

The Royal Exhibitions date from 1863, the National Scholars from 1884. The Free Studentships were added later.

The strict connection between the Science Classes throughout the country and our College will be gathered from the following statement, which refers to the present time—

Twenty-one Royal Exhibitions—seven open each year—four to the Royal College of Science, London, and three to the Royal College of Science, Dublin.

Sixty-six National Scholarships—twenty-two open each year—tenable, at the option of the holder, at either the Royal College of Science, London, or the Royal College of Science, Dublin.

Eighteen Free Studentships—six open each year—to the Royal College of Science, London.

A Royal Exhibition entitles the holder to free admission to lectures and laboratories, and to instruction during the course for the Associateship—about three years—in the Royal College of Science, London, or the Royal College of Science, Dublin, with maintenance and travelling allowances.

A National Scholarship entitles the holder to free admission to lectures and laboratories and to instruction during the course of the Associateship—about three years—at either the Royal College of Science, London, or the Royal College of Science, Dublin, at the option of the holder, with maintenance and travelling allowances.

A Free Studentship entitles the holder to free admission to the lectures and laboratories and to instruction during the course for the Associateship—about three years—in the Royal College of Science, London, but not to any maintenance or travelling allowance.

Besides the above students who have been successful in the examinations of the Science Classes, a limited number (usually about 60) of teachers, and of students in science classes who intend to become science teachers, are admitted free for a term or session to the courses of instruction. They may be called upon to pass an entrance examination. Of these, there are two categories—those who come to learn and those who remain to teach, some of the latter may be associates.

Besides all these, those holding Whitworth Scholarships—the award of which is decided by the Science examinations—can, and some do, spend the year covered by the exhibition at the College.

In this way, then, is the École Normale side of our institution built up.

The number of Government students in the College in 1872 was 25, in 1886 it was 113, and in 1897 it was 186.

The total number of students who passed through the College from 1882-3 to 1896-97 inclusive was 4145. Of these 1966 were Government students. The number who obtained the Associateship of the Royal School of Mines from 1851 to 1881 was 198, of whom 39 were Government students, and of the Royal College of Science and Royal School of Mines from 1882 to 1897 the number was 525, of whom 323 were Government students. Of this total of 362 Government students 94 were Science teachers in training.

With regard to the Whitworth Scholarships, which, like the Exhibitions, depend upon success at the yearly examinations throughout the country, I may state that six have held their scholarships at the College for at

least a part of the scholarship period, and three others were already associates.

So much for the prizemen we have with us. I next come to the teachers in training who come to us. The number of teachers in training who have passed through the College from 1872 to 1897 inclusive is about 600, on an average they attended about two years each. The number in the session 1872-73, when they were first admitted, was 16, the number in 1885-86 was 50, and in 1896-97 60. These have not as a rule taught Science Classes previously, but before admission they give an undertaking that they intend to teach. In the earlier years some did not carry out this undertaking, doubtless because of the small demand for teachers of Science at that time. But we have changed all that. With but very few exceptions, all the teachers so trained now at once begin teaching, and not necessarily in classes under the Department. It is worthy of note, too, that many Royal Exhibitioners and National Scholars, although under no obligation to do so, also take up Science teaching. It is probable that of all the Government students now who pass out of the College each year not less than three-fourths become teachers. The total number of teachers of Science engaged in classes under the Department alone at the present time is about 6000.

I have not yet exhausted what our College does for the national efforts in aiding the teaching of Science.

When you, gentlemen, leave us about the end of June for your well-earned holidays, a new task falls upon your professors in the shape of summer courses to teachers of Science Classes brought up by the Department from all parts of the four kingdoms to profit by the wealth of apparatus in the College and Museum, and the practical work which it alone renders possible.

The number of Science teachers who have thus attended the summer courses reaches 6200, but as many of these have attended more than one course the number of separate persons is not so large.

Research

From time to time balances arise in the Scholarship fund owing to some of the National Scholarships or Royal Exhibitions being vacated before the full time for which they are tenable has expired. Scholarships are formed from these balances and awarded among those students who, having completed the full course of training for the Associateship, desire to study for another year at the College. It is understood that the fourth year is to be employed in research in the subject of the Associateship.

The gaining of one of the Remanet Scholarships, not more than two on the average annually, referred to, furnishes really the only means by which deserving students are enabled to pursue research in the College; as, although a professor has the power to nominate a student to a free place in his laboratory, very few of the most deserving students are able to avail themselves of the privilege owing to want of means.

The Department only very rarely sends students up as teachers in training for research work, but only those who intend making teaching their profession are eligible for these studentships.

I trust that at some future day, when we get our new buildings—it is impossible to do more than we do till we get them—more facilities for research may be provided, and even an extension of time allowed for it if necessary. I see no reason why some of the 1851 Exhibition Scholarships should not be awarded to students of this College, but to be eligible they must have published a research. Research should naturally form part of the work of the teachers in training who are not brought up here merely to effect an economy in the teaching staff.

Such, then, in brief, are some of our Normal School

attributes I think any one who knows the facts must acknowledge that the organisation has justified itself not only by what it has done, but also by the outside activities it has set in motion. It is true that with regard to the system of examining school candidates by means of papers sent down from London, the Department was anticipated by the College of Preceptors in 1853, and by Oxford and Cambridge in 1858; but the action of 1861, when Science Classes open to everybody, was copied by Oxford and Cambridge in 1869. The Department's teachers got to work in 1860, but the so-called "University Extension Movement" dates only from 1873, and only quite recently have summer courses been started at Oxford and Cambridge.

The Chemical and Physical Laboratories, small though they were in the Department's schools, were in operation long before any practical work in these subjects was done either at Oxford or Cambridge. When the College laboratories began about 1853, they existed practically alone. From one point of view we should rejoice that they are now third rate. I think it would be wrong of me not to call your attention to the tenacity, the foresight, the skill, the unswerving patience, exhibited by those upon whom has fallen the duty of sailing the good ship "Scientific Instruction," launched as I have stated, out upon a sea which was certain from the history I have brought before you to be full of opposing currents.

I have had a statement prepared showing what the most distinguished of our old students and of those who have succeeded in the Department's examinations are now doing. The statement shows that those who have been responsible for our share in the progress of scientific instruction have no cause to be ashamed.

Conclusion

I have referred previously to the questions of Secondary Education and of a true London University, soon, let us hope, to be realised.

Our College will be the first institution to gain from a proper system of Secondary Education, for the reason that scientific studies gain enormously by the results of literary culture, without which we can neither learn so thoroughly nor teach so effectively as one could wish.

To keep a proper mind-balance, engaged as we are here continuously in scientific thought, literature is essential, as essential as bodily exercise, and if I may be permitted to give you a little advice, I should say organise your athletics as students of the College, and organise your literature as individuals. I do not think you will gain so much by studying scientific books when away from here as you will by reading English and foreign classics, including a large number of works of imagination, and study French and German also in your holidays by taking short trips abroad.

With regard to the University. If it be properly organised, in the light of the latest German experience, with complete Science and Technical Faculties of the highest order, it should certainly insist upon annexing the School of Mines portion of our Institution, the past history of the School is so creditable that the new University for its own sake should insist upon such a course. It would be absurd, in the case of a nation which depends so much on mining and metallurgy, if these subjects were not taught in the chief national university, as the University of London must become.

But the London University, like the Paris University, if the little history of Science teaching I have given you is of any value, must leave our Normal College alone, at all events till we have more than trebled our present supply of Science teachers.

But while it would be madness to abolish such an institution as our Normal School, and undesirable if not impossible to graft it on the New University, our School, like its elder sister in Paris, should be enabled to gain

by each increase in the teaching power of the University. The students on the scientific side of the Paris School, in spite of the fact that their studies and researches are looked after by fourteen professors entitled *Maîtres de Conférences*, attend certain of the courses at the Sorbonne and the Collège de France, and this is one of the reasons why many of the men and researches which have enriched French science, hail from the *École Normale*.

One word more. As I have pointed out, the French *École Normale* was the result of a revolution, I may now add that France since Sedan has been doing, and in a tremendous fashion, what, as I have told you, Prussia did after Jena. Let us not wait for disastrous defeats, either on the field of battle or of industry, to develop to the utmost our scientific establishments and so take our proper and complete place among the nations.

J. NORMAN LOCKYER

FELLOWSHIPS FOR RESEARCH

THE foundation of Research Fellowships by the Commissioners of the Exhibition of 1851 was in this country of the nature of an experiment. Many people more or less enamoured of the system in vogue at the universities, whereby a man is carried on from one examination grind to another, until his freshness and originality of mind are in great measure lost, looked at the scheme for Research Fellowships with distrust, and an inclination to foretell their failure. There might, it was said, be an able man here and there who is benefited by holding a Research Fellowship and who does good work while holding it, but, in general, maturity of mind and knowledge, and an accumulated fund of experience are necessary for the success of a scientific or literary investigator. There is truth in this, of course, but the scholastic training of the best men is frequently carried so far that all enthusiasm is killed out by examinations, or the mind has become too critical and fastidious for the work of original production or continuous investigation.

These prophecies have been falsified in the most conclusive way by the report of the Commissioners. They say that they have received from academic institutions all over the country unanimous testimony to the success of their system of Research Scholarships, and an analysis of the work done by the Research Scholars and their after careers shows that the success has been full and complete. A number of able young men, fairly well trained in theoretical and practical science, have been chosen from the best students of our provincial colleges and given the means of pursuing research, and therefore also higher study of the best kind, for two or three years at approved institutions at home and abroad. The Commissioners most wisely determine that the whole time of the scholars should be given to the research work undertaken, and have steadfastly refused to sanction the employment of their funds to enable students to prepare for University degrees. The scheme and its conditions were the subject of much criticism. It was objected that by spending time in research the prospects in life of such men would be injured, that it would be difficult for them after to find congenial employment. This fear has also proved groundless. Of the large number of young men who have been sent out by the Royal Commissioners nearly all have obtained appointments in which the knowledge, skill, and, above all, resource and self-dependence they have acquired will be of the utmost value. Many have returned to their old colleges to teach, and to encourage among the students rising among them that zeal for the advancement of science they have themselves imbibed, to be an example ever before the eyes of still younger men, and by their association with rising students to create an interest in scientific progress which the studies of the class-room often fail to arouse. Some

have been appointed to important educational posts at home and in the Colonies, others have gone to direct scientific industries and engineering achievements. In spite of the vacillations of the doubters, the scheme of the Commissioners has succeeded far beyond the expectation of even those who most believed in it, and its remarkable record ought to be widely studied by all interested in the higher education of the country, and especially by those who have the privilege of guiding the policy of our universities.

A similar movement has been started by the youngest of our universities. The University of Wales has now got its curricula into full swing, and has already begun to form its roll of graduates. The question of post-graduate work, and especially of Fellowships for literary and scientific research, was raised at an early period in the discussion of regulations for degrees. There has been no matter before the senate or the court of greater or even approximately equal importance. For upon the decision of the authorities as to whether promising students should after taking their degrees go on to real post-graduate work, or, as is the case at too many places, be encouraged to enter again as undergraduates at some other university, generally either Oxford or Cambridge, rests the whole future of the newer universities as regards the higher learning. If it is regarded as the natural course for a graduate to enter again as a freshman at another university, an important stimulus towards providing the necessary staff and machinery for imparting the best and completest teaching in all subjects will be withdrawn from the colleges. The new universities may do some good to their localities by giving the ordinary education of a professional man, but, under such a policy, they will never become homes of learning and research. In fact these colleges, however well manned, will, as regards the higher work only, take the place of feeding schools for the old universities, and the time and energies of their professors will be occupied with the ignoble task, which might surely be left to the schools and the cramming shops, of striving for the credit of their colleges in the race for a good place in the record of scholarships won or in the list of examination successes. Already one Oxford college has proposed to give scholarships to be confined to the best Welsh graduates, a plan well calculated to increase the number of First Classes in the schools obtained by that college, but certain, so far as it operates in this direction, to degrade the University of Wales. It is to be hoped that this proposal will receive no official countenance from the University itself.

It will be said that the degrees of the University of Wales have as yet little or no market value, and that the best students must go elsewhere to obtain degrees which have. This may be true, a university, like everything else, must begin; but the question arises, how is the university to form its reputation, and to confer a value on its degrees? Surely not by itself sending its best men to colleges on which their home academic training will only help to shed lustre, and to which not only their academic success, but all the credit of their afterlife will be attributed. The duty of the university is to itself, and relates not to the present merely, but also to the future. It has no right to impel or delay any credit or renown there may be a possibility of its attaining; and if there is any lesson to be learned from the history of universities, it is that learning will refuse to grow within academic walls if aims are not high, and if teachers are content to see others doing their highest work.

Also, a new university should pursue this policy of high aims and resolute determination to do all that a university can do for learning and science, from the very beginning. It has a unique opportunity. It is free from the trammels of custom and prejudice, and the claims of vested interests. It can be guided by older institutions,

but the guidance to be obtained from these is almost more often of the nature of warning than of example.

The contention that has been put forward, that this kind of migration to undergraduate work in honours schools elsewhere should be encouraged by the newer, and even some of the older universities of the country, and that they should aid it by the foundation of scholarships and prizes, rests on a confusion of ideas. It may sometimes be a good thing for students who are already graduates to go to Oxford or Cambridge, but the interests served are not those of the parent university, and it is not a thing for the university as such to assist. Funds for such a purpose should be provided by persons interested in the older universities, or in the students to be sent there.

The foundation of Research Fellowships has been undertaken by universities in America with great success. Witness the youthful vigour of Johns Hopkins, and the great and growing vigour of Harvard and Yale, and others in the United States. The plan has been several times proposed in this country, but never until in the scheme of the Commissioners for the Exhibition of 1851 has it had a practical trial. An important pronouncement in its favour was given a few days ago by Mr Simon at Manchester, and there is reason to hope that it may be followed by some practical action at Owens College or in the Victoria University. A fund for five years has been subscribed chiefly in the court of the University of Wales, and at a forthcoming meeting an election of a Fellow will probably be made, and we trust that he will prove the first of a long succession of literary and scientific scholars of native growth. In spite of the proverb, there is much in a name, and it seems to us that no better name than Fellow could have been devised. By rigidly refusing to allow undergraduate work to be undertaken, and giving the style of a Research Fellow to the graduate appointed, the university assures three things: that he shall throughout his tenure of the Fellowship at home or abroad be identified with the parent university, that his status shall be clear, and that no one shall be appointed whose merit is clear and unmistakable. The advantage to the colleges of having a number of young men aspiring to obtain these Fellowships will be immense, especially if, like the Exhibition of 1851 Commissioners, the authorities, where possible, take the successful prosecution of a research as the best evidence of his fitness to hold a Fellowship. Nothing encourages higher work or stimulates a teacher like the presence of young men looking eagerly forward to doing something for the advancement of knowledge. Nothing kills research among teachers like confinement to mere preparation for examination tests, or is more soul destroying for both teacher and taught than the competition which goes on for the longest list of examination successes.

It has been said that men would be encouraged to begin too soon to do original work. This is surely a strange thing to say in the face of the history of learning and science. Some of the greatest discoverers have had little or no training of the ordinary scholastic kind, and it is doubtful if they would have been so successful if they had spent years in grinding for successive examinations. Surely, when a man has taken his B.A. or B.Sc. degree with, say, first class honours in the subject or subjects he has chosen to specialise in, he ought to be ready to make a beginning of research. It does not follow that his work will be unfruitful because his experience has been brief, or his knowledge lacks the width and depth it will subsequently acquire, and acquire all the more surely and truly, if his mind is fixed on discovery or the advancement of learning instead of on the attainment of merely another first class. Training long continued for examinations has killed much intellect; it has created none. Yet, like many another fetish, the

examination system lingers on, and yearly claims its victims.

The University of Wales is to be congratulated in that so far it has recognised no examination post-graduate work at other universities as fit work for the graduates sent out to represent it in the academic world. If higher degrees than that of B.A., M.A. or B.Sc. are required by these, there are the degrees of D.Litt. and D.Sc. of their own university, which it is to be hoped will be given solely as a reward for meritorious research.

It is essential for success in research that the man should be started when his mind is fresh, and he has not had time to acquire that morbidly critical habit of mind which residence at some of the universities seems to encourage so much, and which has been so fatal to the performance of real work by many highly gifted men.

Research will encourage resource, and the application of knowledge to real problems will foster a dependence on self which cannot but be of the greatest value to the possessor. Going out into the world of learning in a self-respecting way, received with due recognition of the position he has attained by the university to which he goes to reside, he will gain experience of the world, and be less apt to show that limitation of mental horizon, and that superciliousness of intellect, so characteristic of many, though happily by no means of all, who have taken high honours at the old universities.

But the best answer to the contention that a long and arduous preparation beyond the Bachelor's degree is necessary for successful research is to be found in the fact that already the contrary has been demonstrated at the Welsh colleges. One young man of great promise did most excellent work in Germany in the difficult field of the study of old Celtic manuscripts, another has made his name known in physical research. Both have returned to their college to teach, and their presence has proved a stimulus and inspiration to others. If the example thus set is followed by others in the Welsh University, and the Fellowship system is allowed a patient and fair trial, the results cannot fail to be of the greatest benefit to all concerned. Knowledge will be increased, the University by respecting itself and its students will be respected and its work will be recognised, and its *alumni* will have no cause to complain of the estimation in which the public hold the credentials they have received from their *Alma Mater*.

A. GRAY.

NOTES.

THE meetings of the International Conference on Scientific Literature, held last week at the Royal Society, came to an end on Thursday. A list of the delegates appointed to attend the Conference appeared in last week's *NATURE*, with an account of the dinner given by the Royal Society in their honour. We hope shortly to give a report of the questions discussed and the resolutions adopted.

THE annual general meeting of the London Mathematical Society will be held on Thursday, November 10. Lord Kelvin has acceded to the request of the Council, and will be nominated for the office of President. Prof. H. Lamb, F.R.S., will be nominated for a Vice-Presidency. The retiring members are Messrs. Jenkins and G. B. Mathews, F.R.S. The former thus severs his long connection of more than thirty years—he being almost an original member. Prof. Elliott, F.R.S., has chosen for the subject of his address, "Some secondary needs and opportunities of English mathematicians."

WITH the object of comparing systems of electric traction suitable for use in London, the London County Council have consented to permit the London Union Tramways Company to

re-construct one section of their lines in the neighbourhood of Hammersmith on the overhead trolley system of electric traction, on condition that two other sections are laid down on the underground conduit plan.

IN his opening lecture to the engineering students at Cambridge on Friday last, October 14, Prof. Ewing intimated that the crowded state of their lecture-rooms and laboratories would soon be relieved. A gift of 5000^l had just been made for the addition of a new wing to the engineering laboratory in memory of the late Dr. John Hopkinson and of his son, John Gustave Hopkinson, who recently lost their lives in the Alps. Dr. Hopkinson's son was to have begun work at this time as a student of engineering at Cambridge. This splendid and welcome gift was made by Mrs. Hopkinson jointly with her son Bertram and her surviving daughter.

THE Harveian Oration was delivered at the Royal College of Physicians on Tuesday by Sir Dyce Duckworth, who, after urging the claims of the college to the consideration of generous benefactors, pointed out that Harvey had definitely charged them to encourage research. The lecturer is reported by the *Times* to have said that what were greatly needed now in England were research laboratories attached to hospital wards and *post-mortem* theatres, and also a select staff of fully trained investigators available for service throughout the Empire. It was surely humiliating that researches were permitted to be made for the public benefit in various parts of British territory by foreigners, while many of their countrymen and countrywomen, owing to ignorance and mawkish sentimentality, were doing their best to debar the training of such men in England. After alluding to the results of recent pathological research in regard to the preventive treatment of tuberculosis, Sir Dyce Duckworth observed that the Roentgen rays had as yet yielded little new information, and their therapeutic influence was not determined, but, according to Rieder, of Munich, the rays emitted from "hard" vacuum tubes killed bacteria. The influence of glycerine in destroying some of the most noxious microbes which gained access to ordinary vaccine lymph was very noteworthy, and he could not but imagine that this agent might yet be found of more extended usefulness as a bactericide. Expressing his private opinion, though he believed it to be shared by the majority of those he addressed, he did not hesitate to stigmatise the recent Vaccination Act as a piece of panic legislation, a lamentable concession to ignorance, fraught with serious peril to the whole community, and unworthy of the duty and dignity of any British Government. He closed with a brief appreciation of Harvey's chief scientific achievements, and of his great guiding principle, devotion to truth.

MR. W. H. FRECE, C.B., F.R.S., will deliver the Inaugural address at the new session of the Institution of Civil Engineers, on Tuesday, November 1. The Council of the Institution have made the following awards out of the trust funds at their disposal for the purpose for original papers dealt with during the year 1897-98. The formal presentation will take place on November 1:—Telford medals and premiums—A. H. Frece (London) and H. C. Stanley (Brisbane, Queensland); Watt medals and premiums—H. L. Callendar, F.R.S. (London), and J. T. Nicolson (Montreal, Canada); George Stephenson medals and premiums—Whately Elliot (Plymouth), W. O. E. Meade King (London), and W. P. Marshall (Birmingham); the Crumpton prize—E. W. Anderson (Erith); Telford premiums—L. B. Atkinson (Cardiff), Henry Fowler (Horwich), W. L. Strange (Bombay), F. J. Waring (London), D. W. Brunton (Denver, U.S.), Wilfred Airy (London), E. M. Bryant (Newcastle-on-Tyne), D. B. Butler (London), and H. V. Champion (Victoria); the James Forrest medal—W. L. Brown (London); Miller prizes—C. E. Wolff (Derby), A. D.

Keigwin (Ashford), Harold Williams (Kington), J. T. Morris (London), H. C. Adams (Birmingham), H. O. Eurch (Bradford), B. K. Adams (Colombo), A. B. E. Blackburn (Wedgebury), Thomas Carter (Newcastle), P. F. Story (Manchester), D. E. Lloyd-Davies (Bewdley), and Wilfred Hall (Corbridge-on-Tyne).

THE Hayden Memorial Award of the Philadelphia Academy of Natural Sciences has been made to Prof. Otto Martin Torell, formerly professor of zoology and geology at the University of Sweden, and late Chief of the Geological Survey of Sweden. Of his works, those which treat of the ice period are the most important. To these belong "Contribution to the molluscan fauna, with a general view of the natural state of the Arctic regions," "Investigations of the Ice Period," and "On the causes of glacial phenomena in the north-eastern portion of North America." Partly by these works and partly by lectures Torell has, in Sweden as abroad, actively assisted in making known the theory that the territory of northern Europe, where great blocks of Scandinavian rocks have been found, was formerly covered by land ice, extending from Scandinavia, like the ice in Greenland at the present time, and not, as had been formerly supposed, by a frozen sea (Eismeer). Dr. Torell is a member of the Royal Society of Sciences of Sweden (1870), of the Agricultural Academy (1872), and of many other scientific societies in Sweden and abroad. He is Commander of the Swedish "North Star," Grand Officer of the Italian Order of the Crown, Knight of the second class of the Russian Order of St. Anna, Commander of the Danish Dannebrog, Officer of Public Instruction, and Officier de la Légion d'honneur.

FROM the report of the Laboratories Committee, presented at the quarterly meeting of the Council of the Royal College of Surgeons of England, held on Tuesday, it appears that since June 3 last 7050 doses of antitoxin, each containing 2000 units, and 2325 doses, each containing 4000 units, for the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board, have been supplied, and all demands fully met. In deference to the researches in connection with the grant from the Goldsmiths' Company, Dr. T. G. Brodie and Dr. Cartwright Wood have continued their investigations and have planned out a further series of experiments for the coming winter. The Committee has awarded to each of them a further sum of 50l. from the research grant, as a recognition of their valuable work. Dr. T. G. Brodie is at present engaged on the chemistry of diphtheria antitoxin, and Dr. Cartwright on diphtheria toxins and antitoxins, and a method of examining water bacteriologically. The demand for antitoxin supplied to general and children's hospitals in London, in accordance with the conditions of the grant from the Goldsmiths' Company for use among the poorer classes of the community, is steadily increasing.

THE death is announced of Prof. Andreas ARRHENIUS, professor of mineralogy and petrography in the Technical High School at Aachen, and of Dr. C. G. GIBELL, professor of botany and director of the Botanical Institute at Turin.

A MEETING of the Physical Society will be held on Friday, October 26. The papers down for reading are: An influence machine, by Mr. W. R. Pidgeon; the repetition of an experiment on the magneto-optic phenomenon discovered by Righi, by Prof. Silvanus P. Thompson, F.R.S.; the magnetic fluxes in meters and other electrical instruments, by Mr. Albert Campbell.

THE following meetings of the Royal Photographic Society are announced:—Technical meeting, Tuesday, October 25, "On the alleged discovery of photography in 1757," by R. B. Litchfield, "On the grain of photographic negatives," by

E. Duncan Stonely. On Monday, October 31, slides will be shown by members of affiliated societies at the exhibition of the Royal Photographic Society.

THE *Athenæum* states that the Vienna Academy of Sciences has chartered the Swedish steamship *Gulfrid* for its projected scientific expedition to South Arabia. The ship is expected to arrive in a few days at Trieste, where the members of the expedition will go on board. The leader of the party is Count Carl Landberg, the Bavarian Orientalist, who has already spent several winters in the district. Dr. H. Müller proposes to devote his researches to the Sabaean inscriptions and the pre-Arabic archæology. Prof. Simony will accompany the expedition as botanist, Dr. Cossmat as geologist, and Mr. Bury will be the leader of the caravan. Dr. Jahn will take as his speciality the study of the Mahra language. Dr. Lajn goes as physician to the expedition.

WE learn from *Science* that, through the generosity of Mr. Cornelius Vanderbilt, the New York Botanical Garden is about to undertake a botanical exploration of the island of Porto Rico. The expedition, which is now being organised, will leave for the New Colony within a few weeks, and will be occupied in collecting museum and herbarium specimens and living plants for at least six months. Inasmuch as very little is yet known concerning the natural flora of the island, it is confidently expected that much of value and interest will be secured, and the collections will furnish the basis of a report on the botany and vegetable productions of our newly acquired territory.—During the past summer much progress has been made in the New York Botanical Garden, in Bronx Park. The construction of the museum building has proceeded rapidly, three fourths of its steel frame being in place, the walls being completed as far as the second story. The warm and wet summer has been favourable to the plants. Much progress has been made in planting the border, which will be completed during the autumn. It will be about two miles in length, and will contain some three hundred and fifty varieties of trees and shrubs.

AN instructive and interesting account of the cultivation of plants yielding Park rubber, the collection and preparation of the rubber, and other aspects of the industry, is given in the *New Bulletin* for October. With regard to future prospects of the rubber from the vast region drained by the Amazon, Mr. Consul W. A. Churchill is quoted to have remarked as follows, in a recent report to the Foreign Office:—"Some people suppose that the supply of Amazonian rubber may become exhausted in the near future. The most competent authorities are not at all of this opinion, but maintain that the supply is inexhaustible, because the *Hevea* is continually being reproduced by nature. Certainly some areas become exhausted when overworked, but when left alone for some time they recover. . . . The area that is known to produce Pará rubber amounts to at least 1,000,000 square miles. Further exploration will, no doubt, show that this area is under estimated." The introduction of the rubber-yielding trees of tropical America to British Possessions in the East was an enterprise in which, more than twenty years ago, Kew took an active part, the expense being borne by the Government of India. A survey of the results of experiments carried out in various places in which the cultivation of rubber has been attempted, is given in the present number of the *Bulletin*.

IN a recent paper on "The accepted altitude of the Aurora Borealis," read by Prof. Cleveland Abbe before the American Philosophical Society, he stated that some observers have seen the light in such positions between themselves and neighbouring objects as to demonstrate that the aurora, like the lightning, may be entirely confined to the lowest stratum. Others have

seen it so located among the clouds that its origin must be placed at or below their level, and, therefore, within a few thousand feet of the earth's surface. On the other hand, those who have calculated the altitudes of specific beams by trigonometrical or equivalent methods have deduced heights of twenty to a hundred miles. Dr Boller has even quoted an altitude of 1243 miles. Prof Abbe remarks that, after reviewing the literature of the subject since the time of Halley, he finds that all methods agree in one fundamental assumption that the observed beams and arches have an individual existence and a definite locus. But this assumption is negatived by the equal frequency of negative and positive parallaxes wherever the parallax method is applied. The only conclusion possible is that the observers do not see the same object, partly because the aurora is too low down, and partly because there are optical illusions due to alignment.

DURING the present year, Dr. Dobereck, Director of the Hong Kong Observatory, published a useful pamphlet on "The law of storms in the Eastern seas," the first part of which was issued in 1886. The work is illustrated by plates showing the different classes of typhoons, and their average tracks and rate of progress, based upon 244 storms registered during the past thirteen years. A translation of the pamphlet by Dr P. Bergholtz, of Bremen, appeared in the *Meteorologische Zeitschrift* for September, thus testifying to the value of Dr Dobereck's investigations to the sea-faring community, and to maritime meteorology generally.

THE special Antarctic number of the *Scottish Geographical Magazine* ought to be widely distributed and read, in order to excite a little more practical sympathy with scientific Antarctic exploration than has yet been shown by the general public. Sir John Murray pleads strongly for a British Antarctic Expedition. At the present moment, he points out, scientific men in Germany are making arrangements, with the approval and support of their Government, for the exploration of the Antarctic in the year 1900. We have been asked to co-operate, at the same time, in this exploration, but our Government has expressed itself unable to support the undertaking, and there is little hope of the necessary funds being procured from private sources. The outlook is thus not at all promising so far as British science is concerned, and unless the unexpected happens, we shall have to stand aside while other countries carry through the great work of examining the south polar area, and reap the results of their enterprise. Sir John Murray suggests that a rich man, or several rich men, should place in the hands of the President of the Royal Society at least 100,000*l.* for the purpose of organising an Antarctic expedition to co-operate with the other expeditions that are preparing to set out in the year 1900. Here is a splendid opportunity for wealth to assist most usefully in the development of knowledge, and earn renown for British science. May the desire to place our country in the fore-front in scientific research, and especially in oceanic explorations, move some generous benefactor to provide means for equipping and sustaining an expedition which will be a credit to the nation and to science. The whole history of Antarctic exploration, including complete reports of the discussion of the subject at the Royal Society on February 24 (see *NATURE*, vol. lvi pp. 420-427), and an excellent map of the south polar regions, is given in the *Scottish Geographical Magazine*, and we trust its publication will produce a practical result.

The August number of the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale* (Paris) is occupied almost entirely by an article by M. L. de Chasseloup-Laubat, on the steamboat service of this country, the United States, Germany and France. The development of steam navigation is traced, and full descriptions given of all the principal steamers which have been engaged in the passenger service of the world, and of some cargo

boats. The article contains detailed particulars of the dimensions of the boats, mode of construction, engines and fittings, speed and draught. In some of the more modern boats, such as the *Campania*, particulars are given of the staff and crew engaged in working the boats, and the quantity of coal and provisions used. From the tables given it appears that for the number of cabin passengers carried the American Line stands first, followed in order by the Cunard, White Star, Hamburg-American and Norddeutscher Lloyd. The German boats carry the greatest number of emigrants. The article is very fully illustrated, and contains several tables as to the time occupied in the different voyages, details of dimensions, horsepower and other matters.

A MAGNIFICENT meteor was observed at numerous points in Ontario, at 8.50 standard time of July 5, and many descriptions of it appeared in the newspapers at the time. Mr. F. F. Payne gives a few particulars of the meteor in the July number of the Canadian *Monthly Weather Review*, which has just reached this country. The meteor was described by observers as a ball of lurid light, apparently about ten inches in diameter, exploding with a loud rumbling noise like thunder, and leaving a long sinuous trail of white vapour, which was visible for at least six minutes afterwards. As is usual there was some apparent disagreement between observers as to the meteor's flight, the popular opinion prevailing that its course must be parallel to the earth's surface, its vertical motion scarcely being considered. From data received, Mr. Payne thinks that the meteor became visible at a height of 125 miles above the earth's surface at a point somewhat to the eastward of Collingwood, over which place it passed near the zenith, its path being inclined a little to the north of west. It apparently exploded over the Georgian Bay in latitude 44° 50', longitude 80° 30', and the observer at Collingwood states that "a loud rumbling noise was heard."

THE question of the determination of the neutral elements of involutions presents considerable difficulties to the mathematician. An important contribution to the solution of this problem is given by M. F. Deruyts, of the University of Liège, in the *Bulletin* of the Belgian Academy. The same mathematician also considers certain properties of gauche curves, his conclusions including among others the following interesting result — "Through $9 - k$ points of space there can be drawn

$$2(k - p + 1) \binom{2n - k + 1}{p} \binom{2n - k}{p - 2},$$

gauche curves of the fourth order having contact of order $(k - p + 1)$ with a given gauche curve of order n , and meeting this curve in $2p - 3$ points."

THE installation of a storage battery of ten thousand cells has enabled Prof. John Townbridge to undertake an inquiry into the nature of electrical discharges in air and gases under conditions which render the investigation practically an incursion into a new region of research. The results of his investigations have on several occasions been referred to in these columns, nevertheless the following *resumé* of certain conclusions, from his paper in the *Proceedings* of the American Academy of Arts and Sciences, vol. xxxiii. No. 21, is of interest. — Beyond 1,000,000 volts the mutual resistance of atmospheric air to electric discharge decreases, and may become as low as 1000 ohms between terminals 2 or 3 inches apart. When the mutual resistance of highly rarefied air is broken down by x-rays, it exhibits less resistance than it does at a mm. pressure when its conductivity is generally considered to be greatest. There are anode as well as cathode x-rays, and these rays exhibit all the peculiarities of the cathode rays. The x-rays can be distinctly produced with an electromotive force of 10,000 volts, and there are indications of them at 5000 volts. Electrostatic induction

is an important phenomenon in that of x -rays; experiments indicate that these rays are evidence of an electromagnetic disturbance, which therefore travels with the velocity of light, and is accompanied by molecular excitation. The mechanism of the production of x -rays appears to be a setting-up of electrostatic lines of induction, and a production of an electromagnetic wave or impulse; the stress in the medium reduces its resistance, and the x -radiations become less and less energetic after a certain interval the longer the Crookes' tube is excited. The behaviour of rarefied media to powerful electric stress is analogous to that of elastic solids to mechanical stresses; a so-called vacuum, which acts as an insulator for electromotive forces giving a spark of 8 inches in air (about 200,000 volts), breaks down under 3,000,000 volts. A single discharge with this voltage through highly rarefied media produces x rays powerful enough to give a photograph of the bones of the hand in one-millionth of a second. During the discharge the apparent resistance of the medium is only a few ohms. In this case the medium seems completely to lose its elasticity, so to speak, and is ruptured, and the elastic solid analogy thus seems to elucidate the question of the electrical conductivity of the ether.

MR. D. E. HUTCHINS, Conservator of Forests at the Cape, recently read before the Cape Town Philosophical Society a paper showing the need and value of extending the area in the Colony at present under forest. Cape Colony stands far below other countries in its proportion of forest, though the climate of the country is such that it ought to have a percentage under forest at least equal to Germany. The following table shows the area under forest in the Colony compared with that in some other countries—

Countries	Area under forest in acres	Percentage under forest of total area of country
Russia in Europe	527,427,000	42
Sweden	42,366,000	42
Austria	46,856,000	31
Germany	34,350,000	26
Norway	18,920,000	25
India	140,000,000	25
France	20,750,000	16
Portugal	1,666,000	5
Great Britain and Ireland	2,790,000	4
Cape Colony	353,280	0.29

Mr Hutchins suggests that plantations should be formed in districts within minimum rainfall limits of 15 or 20 inches per annum. The argument which will perhaps appeal most forcibly to Cape agriculturists is that while the total value of the fruit produced in Cape Colony is 100,000, or less than 269,349, have been paid for wood imported into the Colony during the last two years, nearly the whole of which would be produced in national forests covering an area of about 50,000 acres. That forests can thrive where agriculture is difficult or impossible, is shown by the steeply wooded slopes of the lofty Amatolas, the similarly beautiful forest with its gigantic yellow wood trees in the barren Knysna country, and, perhaps most striking of all, the cedar trees of Clanwilliam, growing on the absolutely bare rocks of the stupendous Cedarberg Range, while at Genadendal an introduced tree, the cluster pine, harder than any of the indigenous trees, is spreading itself self-sown up the rocky mountain-side, in spite of fires, drought, hot winds and climatic vicissitudes, that are too often the despair of the agriculturist.

A PAPER on the "Wanton Mutilation of Animals," contributed by Dr George Fleming to the *Nineteenth Century* for March 1895, has been issued in separate form by the Royal Society for the Prevention of Cruelty to Animals. The paper shows that many mutilations of this kind can boast of a vener-

able antiquity, and are practised in many countries. The practice of removing a portion of the tails of certain breeds of dogs appears to have been instituted as a means for the prevention of rabies, the belief being that the snew which followed the piece bitten off was a worm which produced madness. "Worming," which was performed upon dogs for the same purpose, consisted in the excision of the frenum of the dog's tongue, under the impression that it had something to do with madness. Ear-cropping of dogs has been carried on for two or three centuries. Horses are subjected to tail-docking, ear-cropping, nostril-slitting, and other unnecessary mutilations. The fashion of mutilating horses appears to have prevailed at a very early date in England, and may have been introduced from Germany or Scandinavia. Dr Fleming's descriptions will assist in suppressing these cruel and useless practices.

MESSRS WILLIAMS AND NORGATE'S Book Circular for October, and their latest list of second-hand books (No 10), contain the titles of a number of volumes on scientific subjects. —A more elaborate catalogue, occupying 686 pp., is the new volume of "Naturae Novitates" just issued by Messrs R Friedlander and Son, Berlin. This publication not only contains classified lists of books in many languages on all branches of science, but the works named in it are indexed according to subjects and authors.

THE following official publications from our foreign possessions have reached us—*The Central Africa British Gazette* (published at Zomba) for July 9, containing an interesting report on the cultivation of coffee, compiled by the Commissioner of Agriculture to the Hawaiian Government, Report on the Botanic Gardens and Domains, New South Wales, for the year 1897, by the Director, Mr J. H. Maiden; Annual Report of the Royal Botanic Garden, Calcutta, for the year 1897-98, by the Superintendent, Dr D. Prain, chiefly occupied by a list of exchanges, *Bulletin* (No 15) of Miscellaneous Information from the Royal Botanic Gardens, Trinidad, edited by the Superintendent, Mr J. H. Hart, and consisting of a conspectus of the genera of Ferns and Fern allies of the Colony, and a monograph of the Cyathaceae, comprising the genera *Alophia* (14 sp.), *Homotelia* (15 sp.), and *Cyathea* (25 sp.), *Circular*, Nos. 4-7, of the Royal Botanic Gardens, Ceylon, issued by the Director, Mr J. C. Willis, in which the extension of the rubber cultivation in the island is advocated, especially that of the Para rubber, *Hevea brasiliensis*, which is stated to be well suited to the climate of the low country in the south west of Ceylon.

THE additions to the Zoological Society's Gardens during the past week include a Tantalus Monkey (*Ceropithecus tantalus*, δ) from Lagos, presented by Mr Arthur T. Warren; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr H. W. Mote; two American Flying Squirrels (*Sciurus volucella*) from North America, presented by Mrs Nias; a Bengalese Cat (*Felis bengalensis*) from the East Indies, presented by Mr David J. Munro; a Ruddy Ichnomys (*Hesperetes smithi*) from India, presented by Mr J. Lyons; a Black-headed Lemur (*Lemur brunneus*) from Madagascar, deposited; an Eland (*Oryx canna*, δ), bred in France purchased.

OUR ASTRONOMICAL COLUMN.

THE ANDROMEDA NEBULA.—In this column (September 22, p. 515) we have previously referred to the telegram which informed us that M. Seraphimoff had discovered, near the centre of the nebula of Andromeda, a stellar-like condensation. Writing to the *Astr. Nachr.* (No 3523), he states that the central condensation is no nebulous nucleus, but is quite a distinct star of magnitude 10-11. Measurements with a star of magnitude 11 in the neighbourhood showed that the observed

object is exactly identical in position with that of the old nucleus.

M. Seraphimoff also mentions that an examination of all photographs, drawings and descriptions of this nebula shows that the central part was very seldom referred to as a small star. In the year 1885 numerous observations (*Astr. Nachr.*, vol. cxii—cxv) showed that the central portion had a different appearance to what it now has; at the present time the two small stars appear equally bright and sharp, and this has been corroborated by Profs. Backlund, Belopolsky and Mörner.

That the central position of this great nebula is variable there can be little doubt, but up to the present time only very small differences of intensities have been recorded.

Prof. Pickering, in a Harvard College *Circular*, No. 34, states that a comparison of photographs of the nebula taken with the 8-inch and 11-inch Draper telescopes on September 20 and 21, 1898, with similar photographs taken in 1893-96, fails to show the new stellated appearance.

ATLAS OF VARIABLE STARS.—In a recent number of the *Astr. Nachr.* (No. 3523), Dr. J. G. Hagen describes the arrangement of a new atlas of variable stars, which we hope will soon be published, as it promises to be a very useful addition to an astronomical observatory. When completed the chart will consist of five series, the first three showing, on separate sheets, the positions and neighbouring stars of variables with faint minima, the fourth series of charts is for variables observable with small instruments, and the fifth, for naked eye variables. The sample chart accompanying Dr. Hagen's notice gives one an idea of the completeness of the work undertaken. The zones included in the first three series are -25° to 0° , 0° to $+25^{\circ}$, and $+25^{\circ}$ to 90° , and will cover altogether 150 charts. These charts include a field of one square degree, with an inner square of half the sides. On the outer side of the small square only stars of the BD are inserted. In the inner square all stars are inserted which appear in a 12 inch with a magnifier of 45 and a measurable field of $0^{\circ} 75$.

The variable, with one exception, on each chart is situated in the middle, so that the observer will be able directly to recognise in his field of view which of the stars is the variable in question.

Each chart, further, gives the coordinates of the variable for 1900, with the annual movements, and, in addition, the colour, type of spectrum according to Secchi's classification, and the magnitudes at maximum and minimum. We may mention that each chart will be mounted on good stiff cardboard, and being of a handy size can be held by or placed close to the observer at the eye end of the telescope.

In conclusion, it must be remembered that the publication of this fine series of working charts is a very costly affair, and would probably not have been accomplished had not the benevolent Miss Catherine Bruce taken her usual interest in the progress of astronomical science, and tendered considerable financial help to further the printing of them.

REMINISCENCES OF AN ASTRONOMER.—Prof. Simon Newcomb continues his reminiscences in the third of a series of articles to the October number of the *Atlantic Monthly*. He commences in this number with his visits to Paris to search among the old manuscripts of the Paris Observatory for early observations of occultations which had never been published. We may here point out how important it is to keep a record of every observation that is made, no matter whether at the time it be considered useful or not. The study of what may now seem apparently useless may, for all we know, in years to come, become of vital importance. Such was the case with the old observations of occultations made at the Paris Observatory. "The astronomers had no idea of the possible usefulness and value of what they were recording. So far as we can infer from their work, they made the observations merely because an occultation was an interesting thing to see; and they were men of sufficient scientific experience and training to have acquired the excellent habit of noting the time at which a phenomenon was observed." By means of these old observations "seventy-five years were added, at a single step, to the period during which the history of the moon's motion could be written. Previously this history was supposed to commence with the observations of Bradley at Greenwich about 1750; now it was extended back to 1676, and with a less degree of accuracy, thirty years further still."

Referring to a meeting of the Academy of Sciences which he attended four years later, he says, "In the course of the

session a rustle of attention spread over the room, as all eyes were turned upon a member who was seated rather late. Looking towards the door, I saw a man of sixty, a decided blond, with light chestnut hair turning grey, a slender form, a shaven face, rather pale and thin, but very attractive and extremely intelligent features. As he passed to his seat hands were stretched out on all sides to greet him, and not until he sat down did the bustle caused by his entrance subside. He was evidently a notable

"Who is that?" I said to my neighbour.

"Leverrier."

Prof. Newcomb found Delaunay one of the most kindly and most attractive of men. "His investigation of the moon's motion is one of the most extraordinary pieces of mathematical work ever turned out by a single person. It fills two quarto volumes, and the reader who attempts to go through any part of the calculations will wonder how one man could do the work in a life time."

After the death of Delaunay, who was drowned when out for a sail in a small boat, Leverrier was reappointed to his old place at the Paris Observatory, and to him, as Prof. Newcomb says, "belongs the credit of having been the real organizer of the Paris Observatory. His work there was not dissimilar to that of Airy at Greenwich; but he had a much more difficult task before him, and was less fitted to grapple with it."

LORD LISTER ON EXPERIMENTAL MEDICINE

THE address delivered by Lord Lister at Liverpool on October 8, on the occasion of the opening of the Thompson-Yates Laboratories at the University College in that city, was briefly referred to in our report of the ceremony last week. The complete address is printed in the *British Medical Journal* of October 15, and is reproduced below. It is a statement as to the nature and value of the work to be carried on in the new laboratories, and a dignified vindication of the experimental method in medicine. The facts concerning experiments upon animals are so often presented to the public in a distorted form, that a calm exposition of the true ethical policy of vivisection, such as Lord Lister gives in his address, should have a most beneficial effect.

LORD LISTER'S ADDRESS.

My Lord Chancellor, my Lord Mayor, my lords, ladies, and gentlemen,—When I was honoured by the authorities of the Liverpool College with the request that I would open the Thompson-Yates Laboratories I little imagined that I was asked to take part in so imposing a ceremonial as the present. That it should have assumed such a character, that it should have attracted so large and brilliant a company, including not only many men from various and often distant parts of the country distinguished in medicine and other branches of science, but also noblemen, Church dignitaries, and persons eminent in literature and in politics, seems to me a matter of great importance, full of good augury for the future of the scientific practice of the healing art—in other words, treatment based on real knowledge as contrasted with the blind gropings of empiricism. We seem to have before us to-day clear evidence that the more cultured sections of the British public are becoming alive to the necessity for providing adequate means for the practical study of the sciences which are of the very essence of the knowledge that confers the power to recognise and treat disease. It an engineer is to qualify himself for detecting and correcting anything wrong in a machine of human construction, no verbal description or drawings will give him the regulate information; he must see and handle the details of the mechanism, and watch them at work. And it might seem the veriest common sense that the more practically familiar a man is with the structure and working of that marvellously complicated mechanism, the human body, the better fitted will he be to deal with its disorders. Yet obvious as such a consideration may seem, it is only in comparatively recent periods that its truth has been generally recognised. I am old enough to remember the years before the passing of the Anatomy Act, and I recollect being told as a child of the fendish deeds of Burke and Hare, horrors which it would appear were needed to arouse a prejudiced and apathetic public to the importance of making it legally permissible for the intending surgeon to become acquainted in the only possible way, by

dissection, with the sacred structures which he would be called upon to invade with his knife in the living body. A dissecting room well provided with the needful material for study has since been an essential equipment of every medical school, and a thorough course of dissection is demanded of every medical student. Meanwhile another kind of anatomy than that which the scalpel displays has come into being—the anatomy which the microscope has revealed and is constantly further revealing. This microscopic anatomy both of healthy and of diseased structures has assumed the greatest importance, and like naked eye anatomy it requires special provision for its successful study. The materials to be studied cannot well be obtained by the student in his lodgings, and the processes employed for the elucidation of their minute structure are often of a complicated character which he cannot learn unaided, and require costly apparatus which he cannot provide. The requisite facilities for this work will be amply supplied by the laboratories which are to be opened to day. The necessity for special pathological institutions has long been recognised on the continent, and nowhere has such an establishment been conducted with more signal success than in the Pathologisches Institut of Berlin, presided over for many long years by the illustrious man whom Liverpool is, I am sure, as glad to welcome with reverence as London has been. Many present to day have sat at the feet of Prof. Virchow, but we may fairly anticipate that Liverpool students at all events will for the future be able to dispense with these pilgrimages to Germany. While the minute anatomy of normal and morbid structures will be thus effectively taught in the new laboratories, much may also be done in them to demonstrate and explain the actions of the living organism. I well remember the effect produced upon me as a member of Dr. Sharpey's class in London, by the repetition before us of Bernard's great experiment on the local circulation, and the converse experiment of Waller. The sympathetic nerve in the neck of an animal being divided, the ear of that side instantly became red and hot, and the blood vessels turgid; while on the application of galvanism to the severed nerve the opposite effect immediately followed, the ear becoming white and cool, and the vessels less conspicuous than those of the other side. Thus was impressed upon us, as mere oral teaching could hardly have done, the immensely important fact that the contraction of the arteries as much under the control of the nervous system as those of the muscles of a limb. I need, perhaps, hardly add that the animal being completely under an anæsthetic during such a demonstration no pain whatever is inflicted. In the study of the new science of bacteriology the pathological laboratory will render most important service. The student will see with his own eyes by aid of the microscope the minute living beings which we now know to constitute the essential cause of many infectious diseases, and he will be put through a course of the cultivation of these microbes, which, while it will impress upon him the reality of their existence, and the characters by which the various species may be recognised, will be invaluable as an exercise of the habits of accurate observation and manipulative skill. The new laboratories will also serve as a centre to which practitioners of a wide surrounding district may refer for the authoritative determination of the nature of doubtful specimens of diseased material, which they have neither the needful equipment, time, nor special knowledge to decide for themselves. It is important as the services which the laboratories will render to education and medical practice will be the opportunities which they will afford for research. I had occasion, in the address which I gave two years ago in this city, to refer to some of the benefits which have been secured to mankind by recent biological investigation, and I need not say more on the subject at present, but I would remark that every step in advance in science only opens up wider fields for exploring the infinite resources of nature; and these laboratories will afford ample means for the further prosecution of such beneficent inquiries. Some, perhaps, may be disposed to object to such researches because they involve the sacrifice of animal life. This, however, I need hardly remark, is as nothing compared to what occurs for the supply of food to man. Of animal suffering I need hardly speak, because, in truth, the actual pain involved in these investigations is commonly of the most trifling description. Anæsthesia has come to the aid of experiment on animals, as the electric telegraph did for railways. Anæsthesia enables needful operations to be done without disturbance from the struggles of the animal,

while it affords to the operator the unspeakable comfort of knowing that he inflicts no pain. I am bound to add that antiseptic treatment of the wounds has had a similar doubly beneficial influence. By preventing inflammation it renders healing painless, while it leaves the parts uncomplicated by inflammatory changes, and allows the results of operative procedure to be rightly estimated. I greatly surprised a former Chancellor of the Exchequer when, on a deputation to him on this subject, I explained to him that operations for the removal of parts of the brain of monkeys, which he had imagined to be attended with horrible torture, had, thanks to anæsthetics and antiseptics, been probably from the first to last unattended with a twinge of pain. Such operations thus painlessly conducted have, by indicating the precise functions of different parts of the organ, and thus guiding the surgeon in his operations, already led to the saving of many human lives. While I deeply respect the humane feelings of those who object to this class of inquiry, I would assure them that, if they knew the truth, they would commend and not condemn them. The laboratorists, though they will be formally opened to day, have for some time past been in practical operation, with the result that the Biological and Pathological School of Liverpool is already ranking very high among similar institutions in other parts of the world. As an illustration I may mention the fact that a committee of the Royal Society, with the approval of the Secretary of State for the Colonies, has lately selected a pupil of this school as one of two men specially qualified to undertake investigations in Africa on the deadly malaria of those regions. I cannot conclude these remarks without congratulating the Liverpool College on the mighty addition which these laboratories afford to their powers for usefulness. I believe they may be pronounced, both in structure and equipment, equal to any in existence. I must also congratulate you on having so nobly generous a benefactor as Mr. Thompson-Yates. I trust he will be rewarded by the deep satisfaction of knowing that he is doing incalculable good to mankind. If I may make one more observation, it is that while the laboratories have been so nobly constructed and equipped, there is yet much to be desired as regards the means for maintaining them in efficiency, and if any wealthy inhabitant of Liverpool is anxious to bestow his wealth in some manner calculated to do good to his fellow-men, he could hardly do better than by devoting a portion of his resources to the permanent maintenance of these fine institutions.

MECHANICS AT THE BRITISH ASSOCIATION

THOUGH an admirable President had been secured in Sir John Wolfe Barry, the proceedings in this Section were not up to the usual standard either in interest or importance to the profession. The fact of the matter is that, as in other Sections, too many papers are accepted, involving inordinately long sittings and often tending to hinder due discussion of really valuable papers. Unless the communications are mere notes of some scientific discovery or fact, the programme should be so arranged that not more than four papers are put down for any one day. The organising committee should insist that at least half a dozen copies of any paper intended for reading should be in the hands of the recorder a month before the opening of the meeting; the recorder could then circulate these copies, with a note of the day on which the paper would be taken, amongst those engineers most capable of discussing satisfactorily the facts and conclusions of the author, with a request from the organising committee that they should attend and take part in the discussion. The President would thus have a list of those he could call upon to speak on any paper, and the speakers having had an opportunity of preparing their remarks beforehand, a really valuable discussion would be secured. Few men are able to get up and discuss off-hand a scientific paper, which they have had no opportunity of studying, especially when it has been read often at great speed in an almost inaudible tone, the result is that we have the poor discussions which so often take all the life out of the proceedings in Section G.

At the Institution of Civil Engineers printed copies of the papers are always circulated a week or two beforehand, and no effort is spared to secure the attendance of every one capable of throwing any light upon the subject under consideration. As a

result discussions often extend over two successive meetings of the Institution. Perhaps the organising committee may be able to do something in this line before the next meeting, and renewed efforts should be made to secure papers from the workers in the engineering laboratories which are such a feature now of all our universities and university colleges. All attempts to secure such help during the past few years have met with most disheartening results.

The most important point raised by the President in his valuable address was the suggestion that in order to enable funds to be cheaply raised to carry out the deepening and enlarging of our docks, the great railway companies should practically take over the control of the harbours and docks which they respectively serve. It was pointed out that every year saw an increase in the over-all dimensions not only of ocean liners, but of the ordinary cargo boats, this means that most of the dock authorities will within the next few years have to face very heavy expenditure in enlarging and deepening locks and their water approaches. Sir John doubted if this increased capital would be able to earn a fair interest, and claimed that if they were administered by the railway companies there was more chance of both diminishing establishment charges and of securing a sufficient inducement for the public to invest, on the faith of this new security. He indicated ways of preventing the growth of a dangerous monopoly, but it is very doubtful whether the public would willingly see such an amalgamation; there is already an indictment against the railways of strangling many industries by their excessive charges for carriage of goods, and curiously enough Mr. Forster Brown, in a thoughtful paper on "The economic and mechanical features of the coal question," advocated strongly the State purchase of railways in order to bring about a reduction of freight charges, and thus to make good the ever growing cost of production owing to deeper and thinner seams having to be worked. In the discussion on Mr. Brown's paper several of the speakers reluctantly confessed they were gradually drifting to State purchase as a necessity sooner or later, but the President opposed the proposal very strongly.

The outstanding feature in the proceedings of the Section was the constant cropping up of the important question of facilitating the carrying of the sea board to the factory of the raw products of our great manufactures, and the return transit of the manufactured goods. The extraordinary growth of the manufactures and commerce of Germany during the last twenty years, the still more rapid strides which have been made in the United States during the same period, are forcing us to realise that our supremacy is being challenged in every quarter of the globe, this is the justification of the feverish haste with which schemes are being pressed forward to enlarge our dock facilities, to increase their equipment, and to connect our great inland manufacturing centres to the sea board by canals suitable for sea-going vessels. The cost of carriage must at all hazards be reduced, hence the papers by Mr. C. H. Davison on the new works at Barry Docks (visited by the Section on the Saturday), by Prof. Ryan on Welsh methods of shipping coal, by Mr. Marten on a scheme for the improvement of the waterway between the Bristol Channel and the Birmingham district, and by Mr. Allen on electric canal haulage, and also the paper by Mr. Brown, already alluded to. It was not so much the mechanical and engineering details described in these papers, important though they were, which interested the audiences and gave rise to discussion, but the economic features of the one problem common to them all—the cheapening of the carriage of our raw products and our manufactures. Industrial legislation during recent years, and the upward tendency of wages of skilled labour render inevitable a reduction in some other direction to counterbalance the increased cost of production brought about by the above two tendencies. The two directions in which this reduction can be obtained most readily are in the increase of labour saving appliances in the process of manufacture, and a lessening of the cost of the raw product by facilitating and cheapening its carriage; this latter saving again coming to the help of the manufacturer in the diminishing of the carriage charges on the manufactured goods as they are distributed to our customers. Mr. Brown drew attention to one other direction in which expenses might be cut down, namely in the change of raw rates and taxes, but here he was in reality advocating something which would be of benefit to the next generation and not to ours; his claim that local loans should be repaid within a shorter interval of time than is now necessary

would in fact place, perhaps rightly, a heavier burden on our shoulders. It must in this connection be remembered that much of the great increase in local indebtedness which has begun to alarm some of our statesmen, is due to the borrowing of money for remunerative undertakings, and that as long as the general prosperity of the nation lasts, such municipal undertakings as electric lighting works, waterworks, gasworks, tram-lines, &c., are not likely to become a burden to the community. The money sunk in them is in a similar condition to that invested in ordinary commercial undertakings; the rate-payer pays no increased rates in consequence of them, but in reality obtains many absolute necessities of modern life cheaper than he would were these undertakings in private hands.

The visit to Barry, mentioned above, was a most enjoyable and instructive one, the extraordinary change in the district since the Association met in Bath, when a similar visit was made, was a striking object lesson in the growth of the Welsh coal trade. The new dock was actually opened at this visit, since the three launches in which the party were taken round were the first vessels to steam from the old dock through the connecting cut (the dam closing of which was only partly removed) into the new dock. The splendid caisson for clearing this cut, which was worked with the utmost ease and perfect truth, and the extensive equipment of cranes and appliances for shipping coal were the objects of much admiration on the part of the visitors. Mr. Davison's paper, well illustrated by lantern slides, in which all the difficulties met with in the construction (and as well overcome) were clearly described, had prepared the members of the Section for this visit, which also made Prof. Ryan's somewhat technical paper on the coal-ports in use in South Wales a much more valuable and interesting contribution.

Monday, as usual, was devoted to electrical engineering, when three papers on the application of the electric motor to the engineering workshop, by Mr. A. Siemens, Mr. H. H. Gibbings and Mr. W. Geipel, were read and jointly discussed. The best discussion in the Section at this meeting rose over these three papers, Prof. Silvanus Thompson arguing that in England, by adhering to the continuous current so rigidly, we were dropping behind continental and American engineers, who found no difficulty in their alternating current systems, he claimed that all the difficulties could be easily met and solved, if we only faced them and made use of the experiences of other workers in the field. This contention was hotly denied by Mr. Parker and other speakers, and in the end the matter was left where it began; but, at any rate, it gave an opportunity of publicly thrashing out once more this vexed question. The novel plan adopted at Bradford of hiring out motors to small customers, with the object of increasing the day load at the central station, and also of stimulating small industries will, perhaps, be widely adopted; but it is very questionable whether the charge made for loan of the motor is in any way sufficient to cover depreciation of these somewhat delicate machines. Mr. Proctor, electrical engineer to the city of Bristol, gave some valuable figures as to the comparative cost of working steam and electric pumps for boiler feeding, &c., in central stations; the economy of the electric pump was justifiably shown, especially at light loads, the experiments have, however, hardly been of a sufficiently extensive character to justify absolute conclusions in all cases.

Prof. Silvanus Thompson and Mr. Walker contributed a joint paper on electric traction by surface contacts, in which most of the schemes so far brought forward were described; the experiments conducted by the authors on an experimental line at Willenden were explained, and many of the details described by the help of lantern slides. There was a very scanty discussion, turning chiefly on the possible danger of such studs giving electric shocks (the author explained in reply this was impossible), and on the question of the cost of fitting up such apparatus.

There were two papers descriptive of new instruments—one by Mr. Coker describing a very ingenious instrument for attachment to test bars under torsional stresses in order to measure the small strains or twists, while the material was still in the elastic stage. The instrument had been tried in the mechanical engineering laboratory at University College, London, and found to work well and with complete freedom from all back-lash; it is, however, a delicate and complex to place in the hands of students. The other paper was by Prof. Hele-Shaw on a new instrument for drawing envelopes, and its

application to the teeth of wheels and for other purposes. This communication and also Mr. Forster Brown's are to be printed *in extenso* in the *Proceedings* of the Association. The instrument was a very beautiful one, and the difficult problem it solved had been most carefully worked out, but here again a very poor discussion followed, because no one felt able to criticise the instrument or discuss the advantages or disadvantages of such a piece of apparatus after merely hearing the author's short account; a description with sufficient diagrams ought to have been weeks before in the hands of those anxious to become acquainted with it, and to discuss it.

Amongst other papers dealt with was Mr. Dublin's paper on the treatment of sewage by bacteria, which in the discussion elicited from Sir Alex. Binnie the statement that the experiments he was carrying out for the London County Council led him to believe we were on the eve of most important changes in the treatment of town sewage.

SCIENCE IN RELATION TO TRADE.

DURING the last few years numerous references have appeared in the various reports made to the Foreign Office by Her Majesty's diplomatic and consular officers on the methods adopted by the principal trade rivals of the United Kingdom in their competition in foreign trade abroad, and on the apparent superiority of British traders in meeting this competition. Besides calling attention to this, the Consuls suggest the adoption of certain measures which they consider would be advisable for British traders to take with a view of retaining the pre-eminence of this country on foreign markets.

A selection has been made of the views expressed in some of these reports issued during the period comprised between January 1896 and the present time, and has just been published in a Blue Book.

From the 171 extracts in this publication it appears that the following are some of the causes which are considered as tending to place British trade at a disadvantage in those districts where, especially of late years, foreign competition has been more than usually keen.—

I The disinclination of British traders—

- (a) To supply a cheaper class of goods.
- (b) To be content with a small order at first.
- (c) To study a customer's wishes.
- (d) To adopt the metric system in calculations of weight, cost, &c.
- (e) To grant credit facilities.

II The scarcity of British commercial travellers, in comparison with those of other nationalities, their ignorance of the language of the countries they visit, and the endeavour to supply their place by a lavish distribution of catalogues and other matter printed in English only.

III. The inferiority of the British to the German and American methods of packing.

IV. The additional cost of goods caused by the high rates or freight on British lines of steamers.

V. The frequency of strikes in the United Kingdom tending to cause uncertainty in the delivery of orders.

VI. The development of technical education in Germany and the greater attention paid in schools to modern languages, added to the system of sending young Germans all over the world to acquire a practical knowledge of the language, business habits, &c., of other countries, by means of which they are afterwards able to compete with those countries with a greater chance of success.

The two causes which concern us refer to the use of the metric system and the development of technical education in Germany. On these matters the Blue Book contains the following summary of the views expressed in the reports:—

METRIC SYSTEM.

The Consuls all lay stress upon the uselessness and expense of British exporters forwarding trade circulars and catalogues more or less well-prepared in English, and with English weights and measures calculated in our own currency. British weights and measures are not liked abroad, and are in many cases either not understood at all, or very imperfectly so, and the preference is given to those who accommodate themselves to the metric and decimal systems. On this point the Consul at Naples expresses himself as follows:—"It seems absurd that the first

commercial nation in the world should measure their horses by hands and their dogs by inches, their cloth by ells and their calico by yards; that such impossible numbers should come into their square measure as 304 and 4840, and in their measure of solidity as 1728. And the weights are worse still. It can never be too much impressed upon British traders that all goods for sale on the continent should be marked in metres and kilograms, and all catalogues sent to the continent should be in a language which is understood by the people of the country."

TECHNICAL EDUCATION.

Much has been written respecting the superiority of the German technical education to that of Great Britain, and to this has been attributed the success which is said to have attended German commercial enterprise within the last twenty-five years. That the technical education is better than that in England is denied by many Germans who are competent to express an opinion, having studied the question in both lands, but what they do admit is that the application of this education in Germany is carried out to a more practical and useful conclusion than in England. "Thus," says the Consul at Stettin, "in Great Britain there are numerous public and private schools having a modern side in their curriculum which is an excellent adaptation of what is termed in Germany the 'reil gymnasium'; but in how many English schools is the modern side looked down upon by the head master and consequently by the boys themselves, and the classic side held up as the education which befits a gentleman. Undoubtedly the far greater majority of British lads, on the completion of their education, become what is vaguely termed men of business, and at the present day it is an absolute necessity for the carrying on of that business against the keen competition which, owing to European peace, has manifested itself in foreign lands during the last twenty-five years, that we, as a nation of merchants, should be able to deal with our customers in their own tongues, and for this purpose it is of the utmost importance that the youth of Great Britain should be instructed for the most part in living languages."

Again, attention is called in the reports to the fact that Germans have been gradually paving their way to their present position by quiet individual persistence backed up by special education. It is stated that they are in the habit of going as clerks into British houses at home and abroad and gradually obtaining a thorough knowledge of the British way of doing business, of the courses of production, &c., which they subsequently turn to good account; but some doubts are expressed as to whether any German houses would receive an Englishman in the same way even if he possessed the necessary qualifications. On this point the British Vice Consul at Porto Alegre says, "Germans can generally speak English and French practically and usefully, and were taken into English houses at first because they were content with little, and sometimes even no salary, in order to pick up business. On the other hand, the English clerk usually understands no language but his own, and this deficiency alone would be enough to prevent his being taken on as a clerk in a German house. Twenty or thirty years ago the important export trade of this State was almost exclusively in the hands of British merchants, now it is in German hands."

THE DEVELOPMENT OF THE TUATARA LIZARD

PROF. A. DENDY, professor of biology in Canterbury College, New Zealand, has been engaged for the past two years in investigating the development of the Tuatara Lizard, perhaps the most remarkable animal now living in New Zealand, and the oldest existing type of reptile. A short summary of the principal scientific results obtained was sent to London just in time to be laid before the Royal Society at its final meeting for the session in June last. The memoir itself, containing a detailed account of the general development, with numerous illustrations, has now arrived in England, and will shortly be published. Meanwhile, the following particulars, published in the *Christchurch Press*, will be of interest to naturalists.—The development of the Tuatara presents several remarkable features. The eggs are laid in November, and on Stephen's Island take about thirteen months to hatch, the embryos passing the winter in a state of hybernation, unknown in any other vertebrate embryos. Before entering upon their winter sleep the nostrils of the embryo

become completely plugged up by a growth of cellular tissue. The embryos obtained have been classified in sixteen stages. The early stages of development are angularly like the corresponding stages in the Chelonia, especially as regards the foetal membranes; there being a long canal behind the embryo leading to the exterior, and known as the posterior amniotic canal, which has hitherto been found only in Chelonians, in which it was discovered a few years ago by Prof. Mitsukuri, of Tokyo. Prof. Dendy's results thus strongly confirm the views of those naturalists who regard the *Tuatara* as being at least as closely related to the turtles as it is to the lizards. In the later stages of the development the young animal has a strongly developed pattern of longitudinal and transverse stripes, which disappear before hatching, the adult animal being usually spotted. This observation is a striking confirmation of the general laws of coloration observed in young birds and mammals, which are commonly striped. The eggs which Prof. Dendy investigated were collected for him by Mr. P. Henaghan, principal keeper on Stephen's Island, who showed indefatigable zeal in the pursuit, and made many valuable observations on the habits of the *Tuatara*. Permission was granted to Prof. Dendy by the Government to collect both eggs and specimens for scientific investigation, and the result of Mr. Henaghan's observations has been to show that eggs can be obtained all the year round by those who know where to look for them. For tunately for the *Tuatara* Mr. Henaghan appears to be the only collector who does know at present, and it is to be hoped that before his knowledge is made public the Government will take steps to prohibit the taking of eggs as well as of adults, for we believe the wording of the Act leaves the eggs unprotected. We believe that two German collectors have lately made vigorous, but as yet unsuccessful, efforts to collect the eggs.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr. E. W. Barnes, bracketed Second Wrangler 1896, Class I., first division Mathematical Tripos, Part II., 1897, has been elected to a fellowship at Trinity College.

Prof. Liveing has been appointed a University Governor of the South-eastern Agricultural College, Wye, for five years.

Prof. Flinders Petrie has presented to the Museum of Anatomy and Anthropology nineteen cases of skulls and bones from his excavations at Hierakonpolis, including remains of the prehistoric and earliest dynastic races in Egypt. Prof. Macalister remarks that with this addition the University collections in Egyptian anthropology are probably the largest in Europe; it consists of specimens representing all periods of Egyptian history from prehistoric times down to the battle of Tel-el Kebir.

Prof. Foster will this term give a weekly lecture on the history of Physiology. The first lecture, on Monday, October 24, will be on Claude Bernard.

The Reader in Geography, Mr. Yule Oldham, lectures this term on the geography of Europe and on physical geography.

The University of Sydney is to become affiliated to the University of Cambridge, and students in arts or in science who have pursued a certain course at Sydney will be entitled to the privileges of affiliated students.

MR. JOHN CORBETT, formerly M. P. for Mid-Worcestershire, has offered to give 50,000*l.* for founding and endowing a school of agriculture for sons of tenant farmers for the county of Worcester and district.

ONE of the most recent of the many educational conferences held in the United States during the past ten years, was that of a Committee on Physical Geography appointed under the National Educational Association. As is usual in such cases, the members of the Committee were selected from a wide range of educational institutions, including universities, colleges, endowed schools, and public schools (in the American sense of the term); the expert in the scientific aspects of the subject being thus associated with the practised teacher, who is familiar with the capacities and limitations of young scholars. The preliminary report of the Committee is published in the *Journal of School Geography* for September. It is strongly urged that the physical environment of man should constitute the leading theme of the subject, and that irrelevant items from astronomy,

principles of physics, topics from historical geology, and the classification of animals and plants should be carefully excluded, in order to give time for the proper development of physical geography itself.

THREE members of a series, to be known as the Harvard geographical models, constructed by Mr. G. C. Curtis from designs by Prof. W. M. Davis, have been reproduced in a durable composition by Messrs. Ginn and Co., educational publishers, Boston, Mass., as aids in systematic geographical teaching. The models, 25 by 19 inches in size, may be used in elementary classes in illustration of type forms, such as mountains, peaks, ridges, glaciers, valleys, plains, volcanoes, capes, islands, rivers, lakes, deltas, bays, &c. They also serve for more advanced instruction in rational or explanatory physical geography. The second model is derived from the first by elevation, whereby a low and flat coastal plain is added to the mountainous background. The third is derived from the first by depression, whereby the valleys among the mountains are transformed into bays, and the ridges stand forth as promontories, the coast-line being changed from a simple to a very irregular outline. Many applications of the principles thus taught may be made in all grades of geographical teaching.

THE annual meeting of the governors of University College, Liverpool, was held on Saturday last. The Earl of Derby, president of the college, occupied the chair, and, in moving the adoption of Principal Glascock's report, which was of a very satisfactory character, he said that though much had been done, much yet remained to be accomplished. A pressing need was a proper building for the department of physics, and another very pressing need was a suitable building for the school of human anatomy. Prof. Oliver Lodge deserved to be furnished with adequate means for the important work in which he was engaged. That, however, might be postponed so that the more pressing equipment of a building for the school of human anatomy might be provided. The cost would be about 20,000*l.*, and he would contribute a quarter of this sum if other benefactors were forthcoming. It was announced by the treasurer that besides the 5000*l.* from Lord Derby, he had that day received a cheque for 2000*l.* from Mr. Ralph Brocklebank, for the school of anatomy. Incidentally it was mentioned that the land, buildings, and endowments of University College represented a total value of 400,000*l.*, though the college was founded only in October 1880.

COPIES of the prospectuses of the Day and Evening Classes held at the South Western Polytechnic have been received. This Polytechnic has been built and equipped at a cost of nearly 55,000*l.*, the greater part of which has been raised by voluntary subscriptions. The institute at present possesses a fixed endowment of 1500*l.* annually from the Charity Commissioners. The London County Council will also contribute to the institute an annual sum, depending upon the amount of educational work carried on, and it is anticipated that this contribution will average about 3500*l.* annually. The Principal is Prof. Herbert Tomlinson, F.R.S., and from the prospectuses referred to we see that the operations of the institute are of a kind which will benefit industry and encourage scientific study. The Day College comprises two departments, viz. the technical department, in which students are instructed in the principles of applied science, and the general department, which aims at giving a general education, or special training in science, art, literature, or commerce. The evening classes and lectures are designed to supplement, and not to supersede, the training of the workshop. Among the subjects taught in the mathematical classes we notice the calculus and its application to electrical and other engineering problems. The subjects taught at the Polytechnic cover a wide range, as they also do in other London polytechnics, and they provide all who wish to learn with facilities for doing so.

THE trustees of the late Sir Edwin Chadwick have found in memory of the great sanitarian a course of lectures and demonstrations in municipal hygiene at University College, London, and have devoted a sum of 700*l.* a year to the endowment of a chair of municipal engineering, and a lectureship of municipal hygiene. They have given the further sum of 1000*l.* for the purpose of instruments and appliances, and for the amplification of existing laboratories. The *British Medical Journal* reports that, on Wednesday, October 22, Prof. Osbert Chadwick, son of Sir Edwin Chadwick, delivered an inaugural address opening the first course. After giving a sketch of the history of the

foundation, he observed that relatively little practical instruction can be obtained from lectures alone, and that their utility is greatly increased by a course of practical work. The drawing office is an essential adjunct to academic instruction, engineering is a high art, the art of applying the great sources of power in nature to the use of man, and it is only to be acquired by experience, practice, and observation. The course to be given in municipal engineering will comprise lectures by Mr R. Middleton, on water works, sewage works, and the like. The lectures on municipal hygiene will give elementary instruction as to the cause of disease, methods of disinfection and bacteriology, and other matters which may belong to medicine, but as to which the engineer ought to have information in order that he may be able to design municipal works with intelligence. The Chadwick Laboratory will afford opportunities to the students for practical work in the analysis of air, gas, water, and in other branches of practical chemistry. The trustees have also founded a Chadwick Scholarship, under which the sum of 100*l.* will be paid as an honorarium to a practising engineer taking the student as pupil, or as an alternative the sum will be paid to the student to augment the small salary he may receive as an improver.

A PLEA for increased instruction in geology is put forward by Prof. Logan Lobley in the volume of *Transactions of the South-Eastern Union of Scientific Societies* for 1898. He points out that an elementary knowledge of geology could be given in our secondary schools in part of the time usually allotted for geography, a subject over which much time is worse than wasted in burdening the youthful memory with names and statistics that really mean nothing to the average pupil. At present the place of geology in the early education of the people of this country, whether it be that of the school, the technical college, or the university, is an insignificant one, and unworthy of the general educational importance of the subject. As a remedy, Prof. Lobley proposes that geology should be made an obligatory subject for university pass degrees. He remarks: "The great cause of the general absence of scientific teaching in England is the example set by our two ancient Universities in not requiring some knowledge of what are called the natural sciences for the ordinary pass degree. A graduate of either of these two world-renowned seats of learning may have his Alma Mater, and with honours, and yet be without even an elementary acquaintance with any of these sciences. The consequence is that the great public schools omit science from their obligatory curriculum, and devote their attention to those subjects which are alone required to fit their pupils for obtaining, when at the universities, the pass degree. The practice and the curricula of the public schools again are followed by less important schools, and by the preparatory schools, and the standard of education so set up and made fashionable dominates the teaching of schools generally. Hence it is, in a great measure, that in England education in science is so far behind that of Germany, and we look in vain for geology in the curriculum of an ordinary middle-class school." Prof. Lobley is justified in pleading for increased attention to be paid to geology, but considering that in this country the elementary principles of the subject included under physical geography, which should form the basis of all geographical teaching, are almost entirely neglected in the average middle-class school, there seems little hope at present that geology will find a place in the school curriculum.

On Friday last Mr. Long, M.P., President of the Board of Agriculture, performed the ceremony of opening the experimental farm of Lledwigan, Anglesey, which is rented and managed by the Agricultural Department of the University College of North Wales, Bangor. This college was the first in the kingdom to apply for and to make use of the grant voted by Parliament for the promotion of agricultural education. The area of the farm taken is 358 acres, and the farm is considered one of the best in the country. The aim of the Agricultural Department is to illustrate experimentally the theoretical teaching given at the college. The farm will, therefore, be used as a practising school for the in-college students, as a permanent experimental station where experiments extending for a series of years can be made, and also as a dairy school for the counties of Anglesey and Carnarvonshire. The Professor of Agriculture at the Bangor University College will reside at the farm as the head and manager. He will be assisted by a small committee of practical farmers, who will be entrusted with the sowing, stocking, and cropping of the farm, and with the control of the finances. The Board of Agriculture make a special grant of

200*l.* towards the maintenance of the farm as an experimental and educational centre. A capital sum of 4000*l.* was required for the stocking of the farm. The Drapers' Company have generously made a conditional grant of 1000*l.*, and the college hope to secure the remainder in due time. In formally opening the experimental farm Mr. Long remarked that for a long time practical agriculturists had looked with suspicious apprehension, even with something akin to contempt, upon scientific method and procedure, but that feeling had to a large extent disappeared, and farmers began to realise that, after all, science meant nothing more than accurate knowledge of the causes which produced certain results, and that such knowledge could not fail to be of use to those who had to produce the results as a means of earning their living. In 1888, excepting three agricultural colleges, certain scattered science and art classes, and two local schools in Cumberland and Cheshire, nothing was done for agricultural education. In 1889 Parliament gave a grant of 1630*l.*, and of that Bangor College received 200*l.* In 1889 the grant was increased to 2610*l.*, out of which Bangor received 400*l.* In 1890 Parliament voted 750,000*l.* to the County Councils to be spent on technical education. The Board of Agriculture thereupon took a new departure and applied the Parliamentary grant in general as distinguished from local projects. The amount of the grant has been increased from 2610*l.* to 6800*l.*, and of this sum 5900*l.* is paid to collegiate centres.

SOCIETIES AND ACADEMIES.

LONDON.

Entomological Society, October 5.—Mr R. Trimmen, F.R.S., President, in the chair.—The President announced that the late Mrs. Stanton had bequeathed to the Society such entomological works from her husband's library as were not already in its possession. This bequest was of great importance, and would add to the library a large number of works, many of which, formerly in the library of J. Stephens, were old and now scarce.—Mr J. J. Walker exhibited a black form of *Clytus mystecus*, L. (var. *heteroglyphicus*), taken by Mr. Newstead at Chester, where about 1 per cent. of the specimens were of that variety, also a black variety of *Leptus nubilus*, L., from the New Forest.—Mr. Tutt exhibited an example of *Euschia calandana*, irregularly suffused with black markings, and a series of local varieties of Lepidoptera from Wiltshire.—Mr. S. Image exhibited a specimen of *Acidalia herbaria*, taken in Southampton Row.—Prof. Poulton showed and made remarks on specimens of *Preps octavina-natalensis* and *Preps sesamus*. These strikingly dissimilar insects had been shown by Mr G. A. K. Marshall to be seasonal forms of the same species: from two eggs laid by a female of the first mentioned (summer) form he had bred one imago resembling the parent, and one which was of the blue *sesamus* form.—On behalf of Dr. Knaggs, Mr. South exhibited a series of *Dicrorhampha*, the synonymy of which was discussed by him and Mr. Barrett, *D. flavidorsana*, Knaggs, being shown to be a good species.—Mr. Barrett exhibited and made remarks on specimens of *Loeopis batracella*, Wals., from Folkestone, and the allied species.—Mr. Porritt showed examples of *Acetia subrepens*, obtained by continued selection of the parents, and probably the darkest ever bred in this country.—Mr. Allen exhibited a long series of *Tenocampa guttica*, to show the results of breeding by continued selection, and some remarkable forms of *Abraax grossulariata* from Fitzeale.—Mr. F. Merrifield read a paper, illustrated by a large number of specimens, on the colouring of pupae of *P. mackeani* and *P. nagi* caused by exposing the pupae to coloured surroundings. The pupae of both species were found to be modified by the surroundings of the larva, the effect being extremely marked in the case of *P. nagi*. When the larvae of the latter species were kept in a cage half orange-coloured and half black, all but four of the pupae on the roof of the orange coloured side were green with very little dark spotting, and all the pupae on the roof of the black side were bone coloured with numerous dark-brown spots. He regarded the phenomenon as protective. The exhibit was discussed by Prof. Poulton, who showed a similar series of specimens, and observed that he found the rays of the D. case the spectrum had the greatest influence upon the incipient pupae, the effect diminishing towards either the red or the violet ends. The effect, therefore, appeared to be one of luminosity. Mr. Bateson

stated that his own experience fully confirmed Mr Merrifield's results, but was unable to see how the green coloration of the pupae could be protective, at least in the winter brood. Mr. G. H. Verrall read a paper on *Syrphidae* collected by Colonel Verbury at Aden, the specimens, together with some rare British diptera, being exhibited by Colonel Verbury. Papers were communicated by Mr G. C. Champion on the Clavicorn Coleoptera of St. Vincent, Grenada, and the Grenadines; and by the Rev T. A. Marshall on the British Braconidae, Part viii.

PARIS.

Academy of Sciences, October 10.—M. van Tieghem in the chair.—Observations on the supposed transformation of fat into glycogen by M. Berthelot. Comments upon the paper on this subject of M. Bouchard. The fact of the fixation of oxygen is undoubted, but the author regards the interpretation given to the facts observed as doubtful. It is probable that albuminoids may play a part in this temporary increase of weight. For a man to gain 40 grams of oxygen in an hour, means that nearly all the oxygen respired during that time must remain in the body. The respiratory coefficient under these conditions should be considerably reduced, and further experiments in this direction are very desirable.—Preparation and properties of calcium nitride, by M. Henri Moissan. Starting with pure crystallized calcium, prepared in the manner previously described, it is easy to prepare calcium nitride by the direct combination of the two elements. In the cold, nitrogen has no action upon calcium, but on gently heating a slow absorption takes place, the white metal becoming a bronze yellow colour, the yellow colour attributed to calcium by previous workers being undoubtedly due to the presence of this nitride. At a low red heat the calcium catches fire and burns in the nitrogen, the absorption of the gas being very rapid. The reaction is best carried out in a nickel tube. At the temperature of the electric furnace the nitride is completely decomposed by carbon, calcium carbide remaining in the tube. Water decomposes it with violence, ammonia and calcium hydrate being formed. The suggestion is made that this substance may find a commercial application in the formation of ammonia from atmospheric nitrogen. On the results of Russian geodetic work in Manchuria, by M. Venukoff.—Remarks on the 50th volume of the "Mémoires de la Section topographique de l'Etat Major général de Russie."—Observations of Perseid meteors made at Athens, by M. D. Eggen.—On the investigation of the problem of three bodies, limited to the first power of the disturbing mass, by M. J. Perchot and W. Ebert.—On the energy of a magnetic field, by M. H. Pellat. It has been shown in a previous paper that the expression for the energy of an electrified system undergoes certain modifications if the quantity of heat is taken into account, that the medium gives to or takes from the exterior necessary to maintain its temperature constant during the change. In the present paper a similar expression is developed for the case of a magnetic field.—On a new iodide of tungsten, by M. Ed. Deléage. By the reaction between aqueous hydrogen iodide and tungsten hexachloride a tungsten tetraiodide is produced, WI_4 . The iodide is infusible, cannot be volatilized without decomposition, and is slowly altered by exposure to the air.—On a crystallized tungsten dioxide, and on a tungsto-lithium tungstate, by M. L. A. Hallopeau. By heating lithium paratungstate with hydrogen at a temperature near the fusing point of hard glass, crystallized tungsten dioxide WO_3 is formed.—Thermal study of the sub-oxide and dioxide of sodium, by M. de Forand.—On the combinations of lithium chloride with methylamine, by M. J. Bonafant. Pure anhydrous lithium chloride rapidly absorbs methylamine, and a study of the heats of formation and dissociation pressures shows that three distinct compounds are formed, $LiCl \cdot CH_3 \cdot NH_2$, $LiCl \cdot 2CH_3 \cdot NH_2$, and $LiCl \cdot 3CH_3 \cdot NH_2$. The application of Clapron's formula to the calculation of the heats of dissociation gives results closely agreeing with the experimental determinations.—On a diiodo quinoline, by M. C. Istrati. The introduction of the iodine is affected in the warm, in the presence of sulphuric acid. The iodo-quinoline isolated had the composition $C_{10}H_6I_2$.—On phenyl-phosphoric and phenylene phosphoric acids, by M. P. Gervais. These are obtained by the action of phosphorus pentoxide upon phenols.—The volumetric estimation of acetaldehyde, by M. X. Rocques. Rietz's method of titrating with alcoholic sulphurous acid is modified in such a manner as to increase the accuracy when strong solutions of aldehyde are under examination.—Thermal data relating to isomylmalic acid. Comparison with its

isomer, suberic acid, by M. G. Massol.—Embryos without a maternal nucleus, by M. Yves Delage.—Air and water as factors in the food of certain Batrachians, by M. S. Jourdain. Under certain conditions the eggs of some frogs, during the period of embryonic development, borrow the constituent elements of the young animal from the stock of food materials which it contains, and from the air and water vapour of the surrounding medium.—On the composition and alimentary value of haricots, by M. Balland.—Remarks on an *avours borealis*, observed at Guingamp, September 9, by M. V. Desjardins.

BOOKS, PAMPHLETS, and SERIALS RECEIVED.

BOOKS.—La Fonderie. Prof. Le Verrier (Paris, Gauthier Villars).—Notes on Water Supply. J. T. Rodda (King).—The Structure and Classification of Birds. F. E. Beedard (Longmans).—A Text-Book of Mineralogy. Prof. E. S. Dana, new edition (Chapman).—The Tides and Kindred Phenomena in the Solar System. Prof. G. H. Darwin (Murray).—The Story of Marco Polo (Murray).—Kepler's Traum vom Mond. L. Günther (Leipzig, Teubner).—The Story of the Farm. J. Long (Rural World Publishing Company).—Indiana, Department of Geology and Natural Resources. Twenty second Annual Report (Indianapolis).—Les Ballons-bondés et les Ancêtres. International. W. de Fonvielle, deuxième édition (Paris, Gauthier Villars).—Manuel de l'Explorateur. E. Blum and M. Rollat de L'Isle (Paris, Gauthier Villars).—How to Work Arithmetic. L. Norman (Rugby, Over).

PAMPHLETS.—Report and Transactions of the South-Eastern Union of Scientific Societies for 1897 (Taylor).—A Chemical Laboratory Course. F. Hogg (Darlington, Dodds).—Untersuchungen über die Theorie des Magnetismus. 8c. Prof. E. Dräher and Dr. K. Jordan (Berlin, Springer).—The School Cookery Book. M. Harrison (Macmillan).

SERIALS.—American Journal of Science, October (New Haven).—American Naturalist, September (Ogden).—Notes from the Leyden Museum, April and July (Leiden, Brill).—Himmel und Erde, October (Berlin, Paetzl).

THURSDAY, OCTOBER 27, 1898.

THE FIRST VOLUME OF HUXLEY'S MEMOIRS.

The Scientific Memoirs of Thomas Henry Huxley
 Edited by Profs. M. Foster, Sec.R.S., and E. Ray
 Lankester, F.R.S., Vol. I., Pp. xv + 606. (London
 Macmillan and Co., Ltd., 1898.)

THE editor, whose commands it has long ceased to be possible for an old contributor to gainsay, has desired me to write some notice of the first of these volumes. That his choice should have fallen upon a botanist is perhaps singular, for though there was no branch of biological science to which Huxley was not sympathetic, the bulk of his work is entirely beyond my powers of criticism. Other hands, I understand, will do justice to it as the successive volumes appear.

My task, at any rate, is merely introductory. And in that sense I gladly undertake it. For the appearance of this stately volume is to me a matter of peculiar satisfaction. I think it cannot be doubted that Huxley stood in the public eye as something other than a great man of science. The outside world saw that he had the scientific world at his back when it made him first Secretary and then President of the Royal Society. But why it was so, it may be confidently stated that the vast majority of persons had not the vaguest idea. They knew that he had a great literary gift "at least," said Mr. Balfour at the Memorial meeting, "he will go down to posterity as a great master of English prose"; they knew that he had a singularly lucid and impressive power of oral exposition; they saw that he spent no small part of his life and of his strength in public work and the service of the State most marvelled at the dexterity with which he wielded the perilous weapon of controversy; a necessarily smaller number delighted in the charm with which he played the part of the brilliant man of society; and perhaps some, fewer still, recognised his place amongst the great thinkers of his time.

The splendid gifts which led to success in so many and such varied fields threw the real Huxley which science will hand down to posterity somewhat in the background. I was one of those who were extremely anxious that this side of him should be brought into due prominence by the collection of his scientific work. The project was beset with many difficulties, and it would never probably have been achieved but for the chivalrous loyalty with which the publishers of this journal came to the rescue.

I have stated one reason why, personally, I desired it done. From the point of view of establishing Huxley's place in scientific history, it will be no unworthy *apologia pro vita sua*. But there are others about which a few words may be said.

Not long ago Mr. Lionel Tollemache quoted Mr. Gladstone as saying that while he allowed genius to Romanes he could not concede it to Huxley. The dictum is of no critical or, indeed, of any other value, except as giving an insight into Mr. Gladstone's own ways of thought. For what do we mean by genius? I take it that it is the power of seeing further into the nature of things than is possible with the ordinary insight possessed at the time by

a man's contemporaries. Genius, then, is essentially prophetic. And being so, the validity of its utterances can only be judged by posterity. When one walks in a wood, how can one judge the relative height of the trees, viewed from a distance it jumps to the eyes. For my part, then, I regard it as at once polite and politic to allow genius to all my friends.

But the juxtaposition of Romanes with Huxley suggests some interesting considerations of quite another kind. I knew both pretty intimately; both are dead, and I would not utter a word of criticism which would be unkind to the memory of either. Romanes was peculiarly interesting to talk to, his writing gave me less satisfaction. The bent of his mind was essentially deductive; his mental processes pursued an abstract course aloof from facts, and if he ever descended to them, it was from a sort of condescension to the weaker brethren amongst us. When he arrived at a conclusion, he looked about for facts to verify it. The method was quite logical and correct. Only unfortunately, in common with others who have followed the same line, he never really grasped the fact that biological science is very far indeed from admitting at present of deductive treatment at all.

Huxley, on the other hand, was supremely objective. Animated throughout his life by the most intense "curiosity" in the higher sense, the establishment of accurate observations was a positive passion with him. If facts came into collision with theory, with Romanes it was so much the worse for the facts, with Huxley, so much the worse for the theory. Even I, in turning over the pages of this handsome volume, can trace the dissipation of the mists of hazy transcendentalism in the middle third of the century as Huxley's ardent sun rose stronger and stronger above the horizon. I suppose, but I speak with all diffidence in such a matter, that it was in its full fervour when he wrote the classical paper with which this volume concludes, "On the theory of the vertebrate skull." I myself was too early to come under Huxley's influence in this direction, but I can yet remember the dreary Okenism with which the Comparative Anatomy Lecture-room was pervaded before Huxley's teaching had sunk to the level of the schools.

But the insatiate pursuit of fact, by which I mean the achievement of accurate objective knowledge without prepossession of any kind, was not Huxley's only scientific characteristic. It was accompanied by extraordinary powers of generalisation. He was not a mere compiler of observations. Sparring no pains to see the phenomena accurately, he was equally keen to make them tell their hidden story. Perhaps sometimes he was too keen, but if the story, as Huxley read it, would not always bear subsequent examination, at any rate the original documents on which it was based were always available to test it by.

But there is a curious fascination in turning over the collected work of a man such as Huxley, and tracing the mental paths by which his own ideas shaped themselves. It is not the habit now to study anything but the last and most fashionable text-book. Yet I am persuaded that any biologist who wishes to cultivate accurate habits of thought might profit exceedingly by a careful study of these pages. The method of research

of a great master of the art is laid bare for us; and the acquisition of a right method is a greater thing than a mere knowledge of the results. *πλὴν ἡμῶν πάντες*.

Take as an illustration the interesting indications of the way in which Huxley's mind was feeling its way towards a grasp of evolution. The comparison of the results of philology and embryology in the lecture "On the common plan of animal forms" is curiously suggestive (p. 283). It throws light on what some of us thought a hard saying in his last (as I suppose) public speech made at Oxford, when he said that whether the Darwinian theory remained or fell, the fact of evolution would survive.

It has been said that Huxley made a "stalking-horse" of Darwin, and there is just the amount of truth in this as in every jest. It is evident that Huxley's morphological studies had brought him to the precise point where the "Origin of species" gave him the illumination of which he stood in need. And he seized it with characteristic ardour and enthusiasm. In the case of the cell-theory his mind was not so receptive because not so prepared. "Its value," he says, "is purely anatomical" (p. 220). He could not foresee, and perhaps would not have been justified in foreseeing, that it would supply the future key of our physiology.

And here I must acquit myself of the task which I have reluctantly undertaken. To do any adequate justice to the wealth of accomplished work included in this volume alone is, as I began by saying, wholly beyond my powers. But no intelligent student can turn over these records of Huxley's work without realising the truth of the remark of the editors, that "the progress of biology during the present century was largely due to labours of his of which the public knew nothing." And whatever else such a student may take away from their study, he cannot at least fail to learn how to treat of the most technical matters with the wisdom of pregnant and lucid expression.

W. T. THRELTON-DYER

THE SCIENCE OF APPLIED ELECTRICITY.

Magnets and Electric Currents By Prof. J. A. Fleming. 1p. xv + 408. (London. E and F. N. Spon, Ltd., 1898.)

THIS work, as Prof. Fleming explains in his preface, has grown out of, and may be considered as taking the place of, his well-known smaller work, "Short Lectures to Electrical Artisans," published about twelve years ago.

"In recasting the information in such a manner as to conform more nearly to the present state of knowledge the author still desired to fulfil the original aim of supplying electrical artisans and engineering students with a brief and elementary account of the scientific principles underlying modern applications of electricity in engineering. With this object in view the use of mathematical symbols has as far as possible been avoided, but at the same time an endeavour has been made to give the reader clear notions on the quantitative measurements which lie at the root of all application of electrical facts in the arts."

This endeavour is more than justified by the present admirable volume.

After two introductory chapters, one on magnets and

magnetism describing the simpler properties of permanent and electro magnets, and the other on measurement and units in which the bases of physical knowledge and the principles of "absolute" measurement are explained, the quantitative connection between currents and their magnetic effects is discussed under the heading "Magnetic force and magnetic flux." This discussion might equally well have been entitled "the magnetic circuit," as it virtually amounts to an explanation of that useful conception, and it is appropriately followed by a comparison of the present system of measurement with the "rational" system suggested many years ago by Mr. Oliver Heaviside, the advantages of which are particularly striking in magnetic circuit problems. Chapters iv to vii. deal with electric currents and the theory of their measurement, electromagnetism induction, and electromagnets, with a discussion under the last head of magnetic curves, hysteresis, and the molecular theory of magnetism, chapters viii. and ix. are on the theory of alternating currents and on measuring instruments respectively, and chapter x., a longer one than the rest, is devoted to the various methods of generating currents. The book concludes with an appendix on the measurement of the earth's horizontal magnetic field strength, a table of natural sines, cosines, and tangents, and an index.

From what has been said, it is plain that Dr. Fleming's work is far more than a mere enlarged edition of the "Lectures to Electrical Artisans." It may be best described as a clear and brief—sometimes, we are tempted to think, almost too brief—but always admirably clear account of those parts of electrical theory which should be grasped by the better class of junior student of practical electricity. Such an account has, we venture to think, long been needed. Valuable as are descriptions of such things as Coulomb's balances and Wimshurst machines in the ordinary text-book, the importance of early guiding the thoughts of the youthful electrician into the channels which lead most directly to the regions of his subsequent activity cannot be too strongly emphasised. Life is too short, for all but the very gifted men, to do more than make a distant acquaintance with what, from the electrician's point of view, are the ornamental parts of his science; and it is largely because Dr. Fleming recognises the truth of this, that his book cannot fail to be of very great value to both teachers and students of electrical technology.

OUR BOOK SHELF.

Natural Hygiene or Healthy Blood, the Essential Condition of Good Health and how to attain it. By H. Lahmann, M.D. Translated from the German by Dr. H. Buttner. Pp. v + 253; plates 5. (London. Swan Sonnenschein and Co., Ltd., 1898.)

THE book before us is a learned exposition which aims at two very laudable objects—the reform of clothing and diet, and the banishment of disease. With regard to clothing little is said: the author's children are represented in a state of nudity; this, together with the prescription of constant air baths, and declamations against the amount of clothing worn by man at the present day, makes one think that in his heart of hearts the author regards the entire disuse of all clothing as the beau ideal.

With regard to diet and disease much is said, and much that is both interesting and instructive. For instance, we are informed that although bacilli may occasion disease, they only play a subordinate part. The essential cause of all disease is "dysæmia," or a deficiency or wrong proportion of the "vitalised" mineral constituents in the blood. All dysæmia is dietetic, and arises from too much water (the author, by the way, seems to have an objection to water baths—air baths are the things to have), too much common salt, or the too limited consumption of uncooked fruit and vegetables. Mankind in general, except the author, his children and the inmates of his sanatorium, appear to be suffering from this dietetic dysæmia, and will be a ready prey to the bacillus that settles on them. The whole book is unfortunately pervaded by the spirit of fanaticism, but nevertheless is well worth reading. Although doubtless the importance of the so-called inorganic salts in their combination with organic substances is greatly exaggerated, still the physiological chemistry of the subject is well considered, and the author has spared no pains to collect the results of erudite researches which tend to support his theory. His remarks upon the cooking of vegetables are well worthy of attention, especially in this country. F W T

Applied Geology. By J. V. Eidsen, B Sc (Lond). Part I. Pp vii + 96. (London. "The Quarry" Publishing Co., Ltd, 1898)

THE author of this work states in his preface that circumstances have made it necessary to publish the earlier chapters separately, and that, therefore, these chapters scarcely give an adequate idea of the scope of the completed work.

The part thus published contains little but what can be found, often in much more detail, in such well-known books as the work on field geology by Sir A. Geikie, Mr W H Penning's "Field Geology" and his "Engineering Geology," and the "Treatise on Ore Deposits" by J. A. Phillips and Prof. Louis.

The first chapter deals chiefly with geological surveying, but far too briefly to be of much use. Outcrops are then illustrated by figures resembling those of Sopwith's geological models.

The rule given on p. 14 for ascertaining the thickness of beds by multiplying the breadth of the outcrop, in a direction at right angles to the strike, by the sine of the angle of true dip, should be supplemented by the proviso "having, in case the surface is not horizontal, first reduced the observed outcrop to that which would be observed if the surface were horizontal."

The second chapter is devoted to problems relating to dip and strike, the method of solving which, both by trigonometry and by construction, is clearly explained. In the third chapter unconformity, overlap, curved strata and normal faults are defined and illustrated. In the fourth chapter problems relating to faults are dealt with in a similar method to that made use of in the chapter on dip and strike.

The fifth and last chapter of the part published describes, in the space of twenty pages, stratified deposits of gold, platinum, tin, iron, manganese, aluminium, copper, &c., at various typical localities.

Taking the volume as a whole, it is obvious from the small number of pages devoted to so great a variety of subjects that some matters are inadequately dealt with. On the other hand the book is well illustrated by fifty-seven figures, the explanations are clear, and the work is calculated to be of considerable practical use, more particularly in the case of dip, strike and fault problems.

An ideal work on applied geology should, in addition to taking hypothetical cases, discuss, as far as possible, problems in mining, tunnelling, water supply, &c., which have been actually met with, and should be illustrated

by concrete examples from definite localities in which the theory of the geologist has been tested by the execution of the engineering work. May we hope that we shall not have long to wait for such a work?

Flora of the County Donegal By Henry Chichester Hart Pp xxiv + 392; with a map. (Dublin. Sealy, Briers, and Walker, 1898.)

THE publication of a flora of one of the dampest parts of our islands—one of the most uniformly peat-buried, and one of the hitherto least worked—is pleasing, and the pains evidently bestowed on this book make it welcome. Less than one half of the "Flora" is taken up by the enumeration of the phanerogams, ferns and *Characeæ* of Donegal, of the rest, over sixty pages are occupied by a long report on the climate, and one hundred by a discussion of the distribution in Ireland and Great Britain of the plants of the county. New observations on the altitudinal range of plants, and new statements of their times of flowering are things pleasant to see from the latter, it appears that the "perpetually recurring storms" and the "deficient summer heat" retard the vegetation, so that blossoms appear even later than in the East Highlands. Mr. Hart does not call attention to this, it is a point deserving inquiry. Too long have authors of works such as this been content to copy or to make approximations at dates of flowering. In discussing the vegetation, the lines laid down long ago by H C Watson are carefully followed. As a common basis for comparison of different floras they are valuable, but one can only wish that the splendid chance which so uniform a vegetation offers had led to a consideration of vegetative formations—a subject only just touched upon. This discussion of the vegetation contains several suggestive observations, of which by no means the least in interest is that on the poverty of Donegal in *Crucifera*, *Leguminosæ*, *Umbellifera*, *Compositæ* and *Orchidaceæ* of the last order, *Orchis maculata*, we are told, alone is able to live on the outlying islets; yet these plants, with their tuberous roots, might be expected to be able to tide over bad seasons.

It is a pity that the old error of calling *Neottia* a parasite should appear here, but such errors are rare, and the book, if not strikingly original, will at any rate be serviceable to all who find an interest in the botany of North-west Ireland. I H. B.

The Ribquary and Illustrated Archaeologist Edited by J. Romilly Allen. New Series Vol II. Pp. 288. (London. Bemrose and Sons, Ltd, 1898.)

THIS attractively produced quarterly review of archaeology is "devoted to the study of the early Pagan and Christian antiquities of Great Britain, mediæval architecture and ecclesiology, the development of the arts and industries of man in the past æges, and the survivals of ancient usages and appliances in the present." The volume now before us, containing the numbers published this year, is well up to the high standard of its forerunners. The articles will interest students of the archaeology of Great Britain, and they are so well illustrated that all who are interested in antiquities may derive pleasure from reading them. Many of the articles are noteworthy. Mr. Leader Scott describes a Gallic necropolis discovered in Italy, on a tract of land at the foot of an indentation of Mount Montefortino, near Arcveia (Ancona). In addition to the archaeological aspects, the necropolis affords an interesting study from an ethnological point of view. Mr. Henry Balfour contributes a short paper on the modern use of bone skates and sledges with bone runners. The editor writes on primitive anchors, pot-cranes and their adjustments, and other subjects, Mr. R. A. Gatty describes the objects found in the Barrow at How Tallon; Mr. H. Ling Roth contributes a paper on Benin art, and there are numerous notes on archaeology and kindred subjects.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

Asymmetry and Vitalism.

IN your issue of September 22, Prof. Pearson, referring to the views expounded by Prof. Japp in his interesting address on "Stereochemistry and Vitalism," shows that, if chance be the only factor at work in the replacement of asymmetrical groups in symmetrical molecules, the production in nature of an excess, however small, of compounds of one-sided asymmetry must undoubtedly have taken place. But, ignoring the mechanical interpretation of the phenomenon (thus avoiding the stumbling-block hinted at by Prof. Pearson), and taking, according to present experience, for granted that, in the artificial introduction of asymmetry into a symmetrical compound, equal amounts of two inversely-active bodies are formed, so as to give rise to an optically inactive mixture or compound (in a way recalling to mind the separation of equal and corresponding amounts of positive and negative electricity), other objections may, in my opinion, be brought against Prof. Japp's views.

The point at issue is this: out of inactive material, vegetal and animal organisms are building up substances with asymmetrical molecules, and optically active, such as albumins and carbohydrates. In which fact, joined with the chemists' then ascertained inability to prepare artificial active compounds from inactive substances, Pasteur saw an essential difference between the forces that are acting in living nature and such as are coming into play in our laboratories, he called, accordingly, the former asymmetrical, the latter symmetrical forces. This alleged barrier fell to the ground after the successful preparation, by Perkin and Drupe and by Jungfleisch, of racemic acid from succinic acid, and the separation, by means of a simple crystallising process, of sodium ammonium racemate into dextro- and levo-tartrate, differing by their inverse hemihedral faces, and mechanically separable from one another. Being aware that the spontaneous separation of racemic acid into its two active forms afforded a strong argument against his theory, Pasteur uttered the belief that, even in that phenomenon, some asymmetrical outward agent, such as the organic germs contained in the atmosphere, might be the separating cause; but that hypothesis, inadequately supported by Joubert and Bichat with the doubtful evidence afforded by their experiments, cannot hold its ground against the facts discovered by Scacchi and Wyrouboff, and especially by Van't Hoff and Deventer, respecting the so-called "transition-point" of some double salts, a class of compounds among which the racemates are but a particular case.

On Prof. Japp's view the asymmetrical forces are brought into play in another way and at another moment than on Pasteur's. He contends that, while simple asymmetry (exemplified by dextro-tartrate or levo-tartrate) is caused by asymmetrical actions, double asymmetry, as displayed by racemic acid, is caused by symmetrical actions: no asymmetry comes into play in the latter case, not even when the racemate is separating into its two enantiomorphs, as for every right-handed crystal a corresponding left-handed one is formed. But here is the point. When "the two kinds of crystals are to be picked out, and placed each in a vessel by itself," the intervention of an intelligent force, the intelligent and living (whether mediate or immediate) act of man is needed, as, both kinds having the same solubility, specific gravity, melting point, &c., behave in the same way towards all the separating symmetrical and non-living agents we dispose of in our laboratories. The conscious separation, carried out by man, may be compared with the unconscious one caused by bacteria and moulds, which agents are also able to destroy one kind rather than the other: the common mode of both actions is that they are brought about by living organisms, formed of symmetrical material, and therefore able to act asymmetrically.

Now, granting that, according to Prof. Japp's interpretation of facts, intervention of life cannot be dispensed with in the above separation, I believe that, supposing no substance endowed with molecular asymmetry to exist on our planet, it would be, not merely conceivable, but actually possible to produce as much simple asymmetry as might be desired, by means of an amount of one racemic compound (such as some racemate) liable to separation into active kinds, by the crystallising process, without any interfering asymmetrical force. In point of

fact, after the spontaneous separation (the suitable temperature being granted) into the enantiomorphous crystals, we may always imagine a force, neither intelligent nor living, and acting in a symmetrical way, that would by chance single out one crystal: from that single, asymmetrical crystal (whether right- or left-handed), as was shown among other similar instances by Fischer and Wallach, other compounds can, on introducing asymmetrical groups, be prepared, displaying (without any previous separation into enantiomorphs) simple asymmetry. For, while a racemic compound always comes into existence when we start the synthetic process with a symmetrical and therefore inactive substance, such is not the case when we are operating on active, already asymmetrical compounds, as one active kind rather than its enantiomorph (with respect to the newly-introduced group) may be formed, the other one being partially or totally excluded. The pre-existing asymmetry has a direct influence upon the newly added atoms: asymmetry begets asymmetry, as life begets life. This argument does not only fit the hypothesis that a single crystal be selected; provided that the supposed force act for so short a time as to allow but a small part of the crystals to be removed, there is some chance for their being an excess, however small, of either one or the other enantiomorph to which the above remarks may as well apply.

The following illustration may perhaps convey a clearer idea of the fact stated. Supposing molecular asymmetry to have come on to our planet from outward space (an origin ascribed by some to life), let us imagine one primordial racemic compound to have spontaneously separated into its two enantiomorphs, and these to have been whirled round and scattered about vacant space by some vortex, so as to allow one simply asymmetrical particle to reach our globe. This act, without the intervention of any peculiar force differing at all from such as are acting in chemical synthesis, have originated all the now existent asymmetrical compounds. Some other planet might nevertheless have been reached by a particle of the other enantiomorph; the ensuing molecular asymmetry would accordingly have been the perfect reverse of ours: that celestial body might be inhabited by living creatures akin to ourselves, but built up of dextroglucose albumins; its vine grapes would yield *d*-glucose instead of *d*-glucose, &c. I do not mean to contend that there is any probability of such events having taken place, and am only pointing out that such an hypothesis is in no way absurd or inconceivable. Nay, it might even be enlarged. Although unlikely, a universe (in which our planet might well be included) can be imagined, being formed by pairs of celestial bodies endowed with equal and inverse asymmetry, so as to be comparable with a set of enantiomorphous crystals, into which a mixture of racemic compounds would separate. It matters little whether the enantiomorphs be near one another, as in the case of a crystallising solution, or as wide apart as the celestial bodies we are considering: there is in both cases a determinate point of space one kind of simple asymmetry (the other one being excluded), a result attained without any absolutely asymmetrical action, and especially life, coming into play.

That the way followed by living organisms in their preparation of active substances, differs from the processes followed on in laboratories, is quite another question: the capital point is that, in one way as in the other, the final result is the same, and that the formation of the first asymmetrical group is not necessarily connected with that of the first living particle, as Prof. Japp contends. In my opinion, the problem of spontaneous generation is not likely to be ever reduced to the far simpler question of the origin of molecular asymmetry.

Turn, October.

GIORGIO ERARERA.

I WILL endeavour to reply to the various criticisms which have appeared in NATURE on my address to the Chemical Section of the British Association.

Prof. Karl Pearson points out—that was, of course, obvious—that if only a small number of asymmetric molecules—say twenty—were to be formed under the influence of symmetric forces, there might be a preponderance of either right- or left-handed enantiomorphs, or even that all might be of one kind. He then goes on to suggest that such asymmetric compounds might have been spontaneously formed in the past, and might "be endowed with a power of selecting their own asymmetry from other racemoid compounds," and might thus act as "breeders."

This is a view which, as I have found in private discussion,

is held by several organic chemists. My reason for rejecting it is that it attributes to the "breeding" process (to employ Prof. Pearson's concise, but, as we shall see, not altogether accurate expression) an efficiency which experiment does not justify. I will explain this important point in detail, as those who appeal to the "breeding" process seem to me to do so in a somewhat vague and elastic way.

This influence of already existing asymmetric molecules, or of asymmetric groups within the molecule, manifests itself in two ways, which I will distinguish as *asymmetric induction* and *asymmetric selection*.

(1) *Asymmetric Induction*.—If we introduce into an asymmetric molecule a fresh asymmetric carbon atom, or if we render asymmetric a carbon atom which was not previously so, the asymmetry already present will influence the character of the new asymmetry, and of the two possible arrangements of the new asymmetric carbon atom, one will predominate, or may even be the sole form. This influence, however, is entirely *intramolecular*; all attempts to convert asymmetric induction into an *intermolecular* action have failed. Thus various attempts have been made to obtain an optically active substance by allowing a reaction which under asymmetric conditions would yield a racemoid mixture, to proceed in a solution containing another optically active substance; but this dissolved substance was invariably found to be without influence on the course of the reaction, and the resulting product was optically inactive. This influence, therefore, so far as experiment goes, does not extend from molecule to molecule, although within the molecule it is very powerful.

If the protoplasmic theory of vital synthesis is correct, according to which the molecules of carbon dioxide and other non-living molecules first combine with the living protoplasm and are afterwards eliminated in the form of asymmetric compounds, this asymmetric induction probably determines the asymmetry of the resulting compounds. But even supposing living protoplasm to consist of molecules of which we have no proof—such molecules exercise their peculiar synthetic functions only under the influence of life, and are, therefore, useless as "breeders" for the purposes of Prof. Pearson's argument. Prof. Pearson's twenty non-living asymmetric molecules, formed by the chance play of mechanical forces, would, so far as experiment informs us—although I freely admit that mere negative results are not conclusive—have no more influence on the asymmetry of other molecules formed in their neighbourhood than one toss of a coin has upon another toss.

(2) *Asymmetric Selection*.—This is of two kinds. The first is that discovered by Pasteur, in which the different degree of affinity of one asymmetric base for two enantiomorphous acids (or of one asymmetric acid for two enantiomorphous bases) comes into play, and a separation may be effected, depending on the different solubilities of the resulting salts. But how this process would be available for Prof. Pearson's purpose, one hardly sees. In the most favourable case, his twenty asymmetric molecules would combine with a limited number—twenty, or some simple multiple or sub-multiple of twenty—of molecules from some racemoid mixture that happened to be present, and there would be an end of their action. There is no question of "breeding" here. Their number would not be increased by the process.

The other kind of asymmetric selection, which is a modification of that described by Pasteur, was discovered by Kipping and Pope. It depends on the fact that certain asymmetric substances, when in solution, alter in a different degree the solubility of two enantiomorphs, without actually, as in the previous case, entering into definite chemical combination with them. In this way a partial separation of enantiomorphs may sometimes be effected. But the applications of the method are very limited. Thus Kipping and Pope found that whilst, by means of a concentrated solution of glucose, they could effect a partial separation of sodium ammonium dextro- and laevo-tartrates—substances which spontaneously crystallise separately (i.e. not in racemic combination) at ordinary temperatures—in the case of mandelic acid, which is racemic at ordinary temperatures, no separation was effected, the tendency to form a solid racemoid overcoming any tendency to separation due to the presence of the glucose. Moreover, this action has never been observed, except with concentrated solutions of the selective substance; and it is, therefore, quite impossible that Prof. Pearson's twenty molecules—doubtless in a state of unlimited dilution—could in any way influence the solubility of other substances present.

My contention with regard to this "breeding" question, so far as non-living matter is concerned, therefore is: Asymmetric induction "breeds" only within the molecule, and without thereby adding to the number of molecules, asymmetric selection does not "breed" at all.

In fact, I do not see what Prof. Pearson is to do with his twenty molecules when he has got them. They will not "breed" in the sense he contemplates. On the other hand, if the process which produced them should go further, so as to yield a sensible quantity of substance, both enantiomorphs must be formed; and as the chances are equal in favour of the two asymmetric events; as, moreover, the occurrence of either event does not influence that of the other; and as the number of molecules in a sensible quantity is very great, Le Bel's ratio,

Number of occurrences of event I.

Number of occurrences of event II.

will not differ sensibly from unity.

Several of my critics seem to think that a mere sensible preponderance of one enantiomorph is sufficient. This is not the case unless the minority can be "bred" out of existence; and I do not think that under symmetrical conditions this is possible. We must bear in mind that, in the case of at least 99 per cent of those optically active compounds which are products of the living organism, only one enantiomorph is found. It is the total disappearance of the opposite form which we have to explain.

Prof. Pearson, referring to the hypothesis of the asymmetric carbon atom, says: "Such a geometrical hypothesis cannot give the dynamical explanation of rotatory polarisation required by the physicist." Every chemist, of course, fully recognises this, and in addressing an audience of chemists, I did not think it necessary to introduce so obvious a qualification of my statements. In the present undeveloped state of stereochemistry we are compelled provisionally to treat, as statistical problems which are really dynamical. The atoms are considered as being at rest in the positions of equilibrium about which they actually oscillate or revolve. Or, as Van't Hoff puts it, the problems of stereochemistry are tacitly treated in the form in which they might be conceived to present themselves at the absolute zero of temperature.

Prof. Fitzgerald makes two suggestions, either of which, he considers, would dispose of my contention that single asymmetric forms cannot arise under chance conditions. The first of these he supposes a mixture of two enantiomorphs to separate spontaneously into its right- and left-handed crystalline forms. If life then started from a few such centres, there would probably be a preponderance of one or the other form; "if it started from a single centre, it must have been either right- or left-handed."

In reply I would point out that this spontaneous separation of enantiomorphs is confined to crystalline substances; and I should have thought it fairly obvious that crystalline substances cannot possibly form the organic structural material of living organisms. Can Prof. Fitzgerald imagine crystallised protoplasm?

Prof. Fitzgerald's second suggestion is that life "probably started either in the northern or in the southern hemisphere, and in either case the rotation of the sun in the heavens may be a sufficient cause for a right- or left-handed structure in an organism growing under its influence."

In attributing the origin of the molecular asymmetry of compounds produced in the living organism to the apparent diurnal motion of the sun, Prof. Fitzgerald has been anticipated by Pasteur. I had, therefore, carefully considered the question before writing my address. I do not assign any importance to the negative result of the experiment which Pasteur made with the object of detecting such an influence. Indeed, we need not consider Pasteur's experiment at all, inasmuch as nature has been carrying out for us on this very point an experiment of a similar character which has lasted from the first appearance of life on our planet to the present day—and has equally yielded a negative result. For, if this supposed influence were at work, the asymmetric compounds of vegetable origin produced in the northern and southern hemispheres respectively ought to display

I Prof. Pearson waives any objections to my reasoning "arising from this fact that it is based on a purely geometrical hypothesis as to the constitution of molecules." &c. But even if Prof. Pearson feels inclined to put forward these objections, he will find that I point out, towards the close of my address, that the preponderance is independent of the hypothesis as to what holds good equally of the lamellar crystalline forms of these asymmetric compounds about which there is no hypothesis at all.

asymmetry in opposite senses. But nothing of the kind is observed. Cellulose, starch, saccharose, have the same right-handed asymmetry, each in its particular degree, whether the plant that produces them grows north or south of the equator.

Mr. Bartrum suggests that two enantiomorphs may crystallise from their equimolecular mixture with an unequal distribution of the right and left crystals, that then partial resolution may occur, "roughly on the lines of the distribution of the two varieties of crystals," giving an optically active solution. Unlike Prof. Fitzgerald, Mr. Bartrum does not propose to vivify this crystalline substance offhand; he merely suggests that it may have been "the first ancestor of levo-rotatory protein."

This is vague. As far as I follow its meaning I should read it, "Leave a soluble, crystallisable, asymmetric organic compound, of suitable character and composition, which has been formed and separated by the chance play of mechanical forces, long enough exposed to the action of other matter under the influence of these forces, and it will, in due course, first turn into protein and then come to life." I do not think that this statement misrepresents Mr. Bartrum's position, and I will leave it to speak for itself.

Mr. Bartrum's process of separation is also open to the objection that it would at best yield only an optically active mixture—i.e. with a mere preponderance of one enantiomorph, and as I have already pointed out, that is not a solution of the problem.

Mr. Herbert Spencer considers that I have ignored a universal law of "segregation" which he formulated in 1862 in his "First Principles," and which he there referred to three "abstract propositions" now quoted by him. He asserts that this law of segregation would account for the separation of dextro-protein and levo-protein, if these were once formed; and he instances the formation of hematite nodules and flints in chalk-formations as an illustration of the power of segregation in nature.

I think that Mr. Spencer does not quite realise to what extent enantiomorphous molecules are alike. Every symmetric form of energy (such as heat), and every symmetric material agent, is identical in its action upon two enantiomorphs—whatever happens to the one happens to the other. And in none of these facts is there the slightest violation of the law of the conservation of energy—although Mr. Spencer's corollary to his third proposition would suggest the contrary. As regards the separation of the two, I do not know whether Mr. Spencer would interpret his third proposition to mean that they must be separable by diffusion; but from the foregoing illustration which he gives of segregation in the inorganic world he would seem to have some such process in his mind. In that case I may point out that, as indeed follows from what I have already said, the rate of diffusion of enantiomorphs is the same; no such separation is possible.

If Mr. Spencer will consider this absolutely identical behaviour of enantiomorphs under all symmetric influences, I think he will perceive that the phenomena of "the formation of hematite nodules and flints in chalk formations, or of aliocean concretions in limestone"—phenomena in which only crystalline or crypto-crystalline compounds of symmetric molecular structure are concerned, and which occur under the influence of symmetric forces—are not comparable with the separation of two enantiomorphous colloids such as dextro-protein and levo-protein. Short of some asymmetric influence, nothing could separate these; and I am still waiting for my critics to tell me where, prior to the existence of life, such an influence was to be found.

Prof. Errera writes with special knowledge of the subject of molecular asymmetry, and I have nothing to criticise in his statements, so far as they deal with known fact or accepted theory. Some of his suggestions are exceedingly ingenious. I must admit, for example, that a force neither intelligent nor living—a symmetric mechanism—might be conceived which would pick out a single crystal from a mixture of crystallised enantiomorphs, and thus yield a single asymmetric compound. This is, then, so far a solution of the problem, although not a solution in the sense which I contemplated, since the mechanism cannot be trusted to effect the separation of the same asymmetric form twice running, whereas the living organism, or the intelligent operator, can do so any number of times. This is the essential difference between symmetric chance and asymmetric life. It is a feat which no mechanism could perform, unless its constructor had first embodied in it the idea of asym-

metry, when it would cease to be symmetric, and would be an asymmetric product of living intelligence.

Moreover, as Prof. Errera will perceive from my reply to the arguments of Prof. Fitzgerald and Mr. Bartrum, I do not consider that the separation of enantiomorphous crystals brings us much nearer to the spontaneous formation of those non-crystalline asymmetric substances that build up the living organism. Prof. Errera, it is true, goes a step further in this direction than my other critics by pointing out that—as indeed I emphasised in my address—the further chemical transformation of such an asymmetric compound by the introduction of new asymmetric groups need not yield more than a single asymmetric compound.

Prof. Errera admits that his suggestions as to the manner in which the separation of enantiomorphs may have occurred before the origin of life—thus, that different asymmetric crystals may have been whirled by a vortex into different planets—are not very probable. In fact, all my critics seem to be moving in that unreal world where a fount of type, if jumbled together sufficiently often, ends by setting up the text of *Hamlet*.

In conclusion, I repeat that it is the impossibility of any mechanical (symmetric) force constantly producing the same asymmetric form, or constantly selecting the same one of two opposite asymmetric forms—a constancy which is manifest in the same processes when effected by vital agency—to which I referred in my address. I certainly nowhere used the word "constantly"; but the idea is present throughout.

Most of my critics clearly recognise this impossibility, and therefore seek to avoid the difficulty by supposing only a few asymmetric events—or even, only a single asymmetric event—to occur. The desired result having been obtained, the initial process is assumed to stop. But in making this assumption they seem to me to do violence to all probability. Given a practically unlimited period of time, why should a particular set of mechanical conditions, acting by pure chance in a given way, not act over and over again? One can understand a gambler stopping after a run of luck in his favour; but why should a mechanical process do so?

I see no reason to withdraw any of the conclusions at which I arrived, although, had I to write my address over again, there are parts which, to guard against misunderstanding, I might express differently.

I wish to point out that the term "tetrahedral," used in my paper in describing the asymmetric system of quaternary, is erroneously given in the *NATURE* report (this vol. p. 454, col. 1) as "tetrahedral."

F. R. JAPP.

The University, Aberdeen, October 24.

Potential Matter.

At low me to refer once more to the subject of my letter of August 18, in order to draw attention to two previous investigations with which, at the time of writing, I was unacquainted. Prof. Karl Pearson has, under the title of "Ether Spirits" (*American Journal of Mathematics*, vol. xiii, No. 4), worked out mathematically the theory of matter considered as sources and sinks of fluid, and draws attention to the fact that this theory implies the existence of "negative matter," which may exist outside the solar system. More recently A. Foppl, in a communication to the Munich Academy, dated February 1, 1897 (*Sitzungsberichte d. Akad. d. Wiss.*, 1897, I, p. 93), has published a short paper under the title, "Ueber ein mögliche Erweiterung des Newton'schen Gravitations-Gesetzes." Starting from the idea that there is a difference in kind between the electrical and magnetic fields of force on the one hand, and the gravitational field on the other, because the flux of force through a sphere converges towards zero with increasing radius of the sphere for the electric and magnetic fields, but not, as usually defined, for the gravitational field, Foppl gives the necessary extension to Newtonian law of gravitation in order to remove the distinction. This, of course, implies "negative matter." There is a marked difference between the expression for the energy of the gravitational field on Foppl's hypothesis with that which is derived from the ether squirt theory; but it is not necessary to enter into this question.

There are some points in my former communication, to which previous writers on the subject have, however, not, as far as I know, drawn attention. Among them is the insufficiency of the ordinary hypothesis to account for the rotational momentum

of our solar system which cannot be self-generated, the possibility of having evidence of anti-matter in comet tails and coronal streamers, and the idea of potential matter.

ARTHUR SCHUSTER

Solar Radiation.

AT the conclusion of his British Association lecture on Phosphorescence, Mr. Jackson makes a suggestion with regard to solar radiation which will doubtless receive due attention from those who are interested in solar physics. It is one of especial interest to me because, by an entirely different train of thought, Mr. Jackson has arrived at a possible explanation of the relation between sun-spots and terrestrial magnetic disturbances which is practically identical with a suggestion I have recently put forward in a paper on "The cause of the darkness of sun-spots," published in the *Astrophysical Journal* (April 1897).

In this paper I attempted to show that absorption by relatively cool material offers no satisfactory explanation of the darkness of sun spots, and that the spectroscopic evidence is really quite compatible with a relatively high temperature even in the umbra of a spot.

But in abandoning the absorption hypothesis, one is brought face to face with an apparent contradiction of Kirchhoff's law. Thus it is certain from the low mean density of the sun that the interior region under enormous pressures must be vastly hotter than the photosphere. If, therefore, spots are really breaks in the photospheric clouds through which we obtain a glimpse of the interior, why is it that the radiation from them is apparently so much less intense than from the photosphere? The clouds of condensed matter may, of course, possess a much higher radiating power than the gaseous mass below them; but this, according to Kirchhoff's law, should be entirely compensated by the enormous depth of the feebly radiating interior mass.

To meet this difficulty I suggested that the radiation from the interior, at the transcendent temperatures which must exist even a few thousand miles below the sun's visible surface, may possibly not be apparent as visible light, but may occur in wave-frequencies of a higher order than the known spectrum; and "may be effective in producing those magnetic disturbances which are characteristic of large umbrae."

Mr. Jackson however, if I have rightly understood him, supposes that it is not so much a question of temperature as of molecular structure that determines the wave-frequency of the radiation, and he regards the light of the photospheric clouds as a phosphorescent glow induced by undulations of a high order of frequency which are emitted by the simpler uncondensed materials. The condensed clouds containing more complex molecular groups acting as a screen, and converting the inviolable radiant energy of high frequency into ordinary light.

With regard to this interesting speculation, one would like to know more particularly what is the nature of the evidence on which the idea is based that very simple molecular systems give rise to undulations of high frequency? There can scarcely be any analogy between the behaviour of matter in highly exhausted tubes and under the enormous pressures and temperatures which must exist within the photosphere.

The case of the phosphorescent lines is an exceedingly interesting one, but is there any ground for the belief that the line obtained from organic salts, and giving a blue phosphorescence, is really simpler in molecular structure than a line which glows red?

J. EVERSHED

Kenley, Surrey, October 14.

Hibernating Reptilian Embryos.

WILL you allow me space to correct an error that has crept into the account given in the *Christchurch Press*, and reprinted in the last number of *Nature* (p. 609), of Prof. Dendy's successful investigation of the development of the egg of the Tuatara lizard, *Sphenodon*.

The fact of an embryo hibernating within the egg was not, as stated, unknown among vertebrates, an exact parallel being offered by no less well-known a reptile than the European pond-tortoise (*Emys orbicularis*). This was first observed in Austria, in the last century, by Maravigli, whose statement has been corroborated by Muran in 1857, eggs laid in his garden at Klief in May hatching eleven months later, and by Rollinat in 1894, the latter author concluding that hatching does not, as a

rule, take place in France before the twenty-second or twenty-third month after oviposition.

I need hardly add how pleased I feel at the result of Prof. Dendy's investigations showing the close resemblance which the development of *Sphenodon* bears to that of the tortoises, since I believe to have been the first systematic to follow Cope (1855) in placing the *Rhynchocephalia* in close proximity to the Chelonians with the remark: "The affinities of the *Rhynchocephalia* to the Chelonians are at least as great as to the *Lacertilia*" (*Cat. Chelon.*, 1859, p. 1).

G. A. BOUIENGER.

British Museum (Natural History), October 23

Organic Variations and their Interpretation

I SHOULD be glad if Mr. Cunningham would tell us upon what evidence he founds his opinion that, in crabs, "it is certain that the number of ecdyses depend on age, not on size."

This assumption lies at the base of Mr. Cunningham's criticism of Prof. Weldon's arguments; but, even apart from that, the matter is one of such general biological interest that I hope he will respond to an invitation to substantiate a view which to me, at any rate, is altogether novel. I have always understood that exuviation was a phenomenon essentially connected with the process of growth in Crustacea rather than with the mere passage of time, and it is needless for me to remind Mr. Cunningham of the familiar facts and published statements which support this generally accepted view. Will Mr. Cunningham, on the other hand, tell us how many cases of exuviation, unaccompanied by growth, he has observed among Crustacea?

Unless Mr. Cunningham can revolutionise the present state of knowledge on this subject, his criticism, based on the greater relative growth of young crabs in 1893 than in 1895 and 1896 (which in itself is probable enough), falls to the ground; for he admits that "change in the proportions of a crab occurs only at the ecdysis." In assuming that, on the whole, similarity of size in young shore-crabs indicates an equal number of moults, Prof. Weldon appears to me to be quite in accord with our present knowledge of the subject. Certainly—to modify Mr. Cunningham's phrase—the frequency of exuviation in different *Carinini* corresponds much more closely with their relative growth than with the periods of time occupied.

Plymouth, October 22. WALTER GARSTANG.

Wall Mirages

MR R. W. WOOD, who describes a mirage on city pavements, in *Nature* of October 20 (p. 596), may like to refer to the second volume of *Nature* (p. 337, August 25, 1870), where he will find an account of mirages seen by looking closely along a wall, which was exposed to a hot afternoon sun. The mirage must be very common, and needs only looking for. Mr. Wood's interesting letter may lead others to photograph this curious phenomenon in our own country. A wall will be easier to deal with than a pavement.

Leeds, October 22. C. T. WHITMELL.

A White Sea

I HAVE received several letters respecting this phenomenon (see p. 496), and have distributed the samples of water to two gentlemen who were desirous of examining it. Will you permit me to say that subsequently I received another application from a bacteriologist on the continent, and that the letter was unfortunately lost before complete pursuit. Hence my failure to acknowledge its receipt.

JAMES W. BARRITT.

22 Cavendish Square.

SURFUSION IN METALS AND ALLOYS.¹

THE author points out that metals and alloys may be maintained in a fluid state at temperatures which are many degrees below their true freezing points, and states that this fact has been but little studied. As regards salts, the question of surfusion has recently received much attention. Ostwald (*Zeit. für Physik. Chem.*, 1897, vol. xxii. p. 3) has shown, as the result of an investigation

¹ "Surfusion in Metals and Alloys" by Prof. W. C. Roberts-Austen, C.B., F.R.S. (Abstract of a paper read at the Royal Society, May 26.

of great interest, that a very minute quantity of a solid will cause a mass of the same substance to pass from the surfused to the solid state. His work, moreover, has led him to distinguish between the *meta-stable*, or ordinary condition in which surfusion takes place, and the *labile* condition which occurs at temperatures much below the melting point. Ostwald's paper, and one by M. Brillouin (*Ann. de Chim. et de Phys.*, 1898, vol. xii. p. 264), on the theory of complete and pasty fusion, led the author to offer the Royal Society the results of his own experiments on the surfusion of metals.

Metals do not appear to have been examined from the point of view of surfusion until the year 1880, when some excellent experiments on the surfusion of gold were made by the late Dr A. D. van Riemsdijk (*Ann. de Chim. et de Phys.*, 1880, vol. xx. p. 66), by whose early death, which occurred last year, Holland has lost a skilful physicist. He pointed out that —

"Faraday, in his memoir on regelation, published in 1858, stated that acetic acid, sulphur, phosphorus, many metals and many solutions, may be cooled below the freezing temperature prior to solidification of the first portions" ("Experimental Researches in Chemistry and Physics," p. 379). On the other hand, in their treatises on physics, Danguin (vol. i, 1855, p. 892) and Jamin (vol. i, 1859, p. 105) mention tin as the only metal which is capable of remaining liquid at a temperature 2° below the true solidifying point of the metal.

FIG. 1

FIG. 2

Van Riemsdijk's contribution to the subject of surfusion of metals consisted in showing that the well-known phenomenon of *déclat*, the brilliant flash of light which often attends the solidification of the metal in the ordinary assay of gold, is really due to surfusion. He also pointed out that surfusion could be either stimulated or hindered by suitably modifying the conditions, but he made no attempt at thermal measurements. It was not until ten years after van Riemsdijk's work that the recording pyrometer, which the author submitted to the Royal Society in 1891 (*Proc. Roy. Soc.*, 1891, vol. xlix. p. 347), enabled such measurements to be readily effected.

After a brief description of this appliance, the nature of which is now well known, it is stated that the freezing point of a metal, or the initial freezing point of an alloy, may be represented by one or other of three typical curves. Two of these are shown in the accompanying figures, which indicate the nature of the curves, traced by the recording pyrometer. Fig. 1 shows the freezing point curve of a pure metal, the horizontal portion, a, b , indicating the actual solidification of the mass, the sharpness of the angles at a and b attesting the purity of the metal. The initial freezing point of most alloys would resemble Fig. 1 in having the corner a sharp, while the point b is generally rounded off.

The third type of curve, which may be a modification of the other two types, indicates the occurrence of surfusion, the bend at a , Fig. 2, showing the amount of surfusion which was observed. The author has detected pronounced cases of surfusion not only in gold, but in copper,

bismuth, antimony, lead, and tin. Surfusion, moreover, is not confined to pure metals, and he showed in 1893, that the eutectic alloy in the bismuth-copper series presents a marked case of surfusion. In order to study surfusion, it is necessary to make the galvanometer (to which the thermo-junction is attached) very sensitive. The method of effecting this is described, the thermo-junction itself being in all cases suitably protected and placed in the cooling mass of metal or alloy. A curve, traced by the aid of such a sensitive method, if it represents the surfusion of a metal or an alloy, does not merely show a slight depression as in the case of pure gold shown at a , Fig. 2. The slight depression becomes a deep dip. It is, in fact, possible by the methods described by the author to ascertain what takes place during the surfusion of an alloy, and the results are shown in two plates appended to the paper. From these plates one illustration (Fig. 3) has been selected. It is the autographic representation of the surfusion of an alloy of 64 parts of

FIG. 3.—64 tin, 36 lead

tin and 36 parts of lead. The line a, b represents the surfusion of the mass which, as the scale shows, fell 10 degrees below its true point of solidification before it actually became solid. The solidification of the mass is recorded by the horizontal line c . This autographic record also shows that something happened during surfusion, for there are points at d and e . These proved to be due to the falling out of lead at d , and to its having to be remelted at e . The entire mass then became solid.

Experiments such as the one described have enabled the author to trace the crossing of solubility curves of certain metals in each other in the same way as had previously been effected in the case of salts by H. le Chatelier and by Dahms.

This crossing of the solubility curve of lead and tin is shown in Fig. 4, but for a description of it reference must be made to the original paper.

The first experimental evidence as to the identity of the behaviour of saline solutions and metallic alloys as regards selective surfusion, has thus been afforded by

Prof. Roberts-Austen. The question is, as he shows, one of much theoretical interest, and should lead to further experiments.

The author then adopts a method previously used by Spring (*Bull. Acad. Roy. Belg.*, vol. xviii., 1894, p. 40). He proceeds, after quoting experiments by Ostwald, Demarçay, Pellat, Colson and Russell, to show that alloys may be formed by the vaporisation of certain metals *in vacuo* at so low a temperature as 50° C. He

FIG. 4.—Freezing point curves of lead-tin alloys

concludes by pointing out that the results given in the present paper reveal additional points of similarity between the behaviour of alloys and that of ordinary saline solutions. He trusts, therefore, that it may be useful as a continuation of his investigation on the "Diffusion of Metals," which formed the subject of the Bakerian Lecture of 1896.

THE NEW PHYSICAL LABORATORY OF THE OWENS COLLEGE, MANCHESTER

THE laboratory of which the foundation-stone has been laid, on the twenty-fifth anniversary of the occupation of the present Owens College buildings, will be the largest and most completely equipped in this country. It stands on a separate plot of ground adjoining the Owens College site, and consists of a main building and a large annexe, the latter being more especially intended for electro-technical work. The principal building is 100 feet long and over 60 wide, and consists of a basement and three stories. The diagram gives the comparison as regards dimensions with some of the principal

laboratories abroad. The squares represent square area of floor space of the working rooms, i.e. all corridors, cloak-rooms, &c., are excluded, and the floor space of the different stories added up. It will be seen that the only laboratories materially larger than the proposed building are those of Baltimore and Darmstadt. But provision has been made for future extension, the plot of ground secured by the College being sufficiently large to double, if necessary, the size of the building.

NO. 1513. VOL. 58]

The cost of the building with fittings and new apparatus is estimated at 30,000*l.* Of this sum 17,000*l.* has been subscribed, in one sum of 10,000*l.*, one of 5000*l.*, and two of 1000*l.* In the ample provision for research work has been made. Two large rooms, for instance, are exclusively devoted to spectroscopic work, one of them being arranged to hold a large Rowland grating. It is intended to have at least one room set aside for constant temperature work, and to establish a small plant for the production of low temperatures. An electro-technical laboratory will be added, in which large currents will be available for electric furnaces.

One of the features of the laboratory will be a carefully planned system of ventilation combined with an attempt to exclude dust, as far as possible, from all rooms, and especially from the instrument cases. The plenum system, much used at present, had to be rejected, because it takes up too much valuable basement space, because it is ineffective as regards exclusion of dust, and because the inevitable noise and mechanical shaking due to the fans would have seriously interfered with the work of the laboratory. The architect is Mr J. W. Beaumont, who, before finally drawing the plans, was sent by the Council of the Owens College to visit the principal modern laboratories of Germany.

In seconding a vote of thanks to Mr. Henry Simon for laying the foundation-stone, Prof. Schuster gave a short description of the building. In the course of his remarks he said—

In the general plan of the building I have departed considerably from that adopted in some of the recent continental buildings. The designer of a laboratory may take either one or other of two opposite views, according as he wishes to differentiate as much or as little as possible between different rooms and between different classes of students. The present tendency is to adopt the former course, and to draw a rigid line of separation between the rooms set aside for elementary and for advanced work. This system is carried out to such an extreme in one of the most recent and, in some respects, most perfect of German laboratories that a separate division with a staircase of its own is provided for the elementary students, who thus can never be brought into contact with their more fortunate colleagues admitted to the main part of the building.

I have adopted the opposite course, for I consider that a free intercourse between different classes of students is of great benefit and educational value. My object has been to throw the students together and not to separate them, so that the

beginner may occasionally see his more advanced colleagues at work, and the latter will have an opportunity to overlook and sometimes to assist their juniors. To some extent, the separation of students is necessitated by the requirements of space and apparatus, but we may do much to minimise instead of exaggerating the division.

Most of the rooms devoted to the highest kind of work are sufficiently large to accommodate several students. In this matter also I have not followed the practice now in fashion, which favours small rooms for single students. It is no doubt

very convenient to those engaged in original investigations to have undivided command over a space in which they are absolutely undisturbed, in which they may leave their apparatus secure against interference. But having regard not only to individual convenience but to the general good of the laboratory, my experience leads me to believe that the advantage lies with the older and less luxurious times, when space was valuable and a number of men were forced to work together.

I remember the old laboratory of the great Helmholtz, in which we were about half a dozen students carrying on research work in a room in which each of us had to be satisfied with a table.

The Professor used to spend an hour a day with us, conversed with each about the work he was doing, and we could all daily hear him speak and give his advice about a variety of subjects in a way which would have been impossible if we had been shut up in single rooms. We became interested in each other's work, and thus increased our experience and obtained a much broader view of the range of physics. I consider the experience thus gained to have been quite invaluable, but curiously enough the Professor did not himself realise the importance of this mutual intercourse, and a few years later, when he drew up the plans of a new laboratory, he adopted what has with reason been called the principle of solitary confinement, each student having a separate small room assigned to him. The result, I think, showed that the advantage secured by the increased privacy was too dearly paid for. It became impossible for the Professor to make the round of all the rooms each day, he ceased to exercise the same supervision as before, and the students, left to themselves, soon only looked after their own individual interests and lost touch with their comrades.

A great deal of attention has recently been given to the splendidly equipped laboratories of the German polytechnic schools, and the remarkable development of German industry is not unnaturally ascribed to their influence. But if we wish to emulate these laboratories, we should remember that the polytechnic school is only one part of a complete system of education which is not possible in this country. We should inevitably be led to failure if we tried to solve the educational problem of this country by importing one particular type of institution, without regard to the previous training of the students attending it, and what is more difficult to ascertain, their future career or position in life.

We shall do better if we attack the problem by forming a clear idea as to whom we want to educate, and then doing the best we can with the material at our command.

In the industrial life of a country two distinct classes of men are needed. There are in the first place the leaders, on whom all the burden of further progress will fall. We look to them for future discoveries and inventions, and we must provide them with the proper tools to work their way, and weapons to overcome their obstacles. Though necessarily few in numbers, these men who are specially endowed to serve their country by their intellect and enterprise should receive our first attention. At first sight their education seems easy enough, for what can we do more than lead them up to the highest level of their subject. Yet there is one danger so serious that I believe it lies at the foundation of the distrust with which the greater part of the industrial community still looks upon education. The want of confidence in the teaching profession, which is a national characteristic to be reckoned with, because probably not to be cured, has had the effect of establishing a rigid system of teaching and examining, which undoubtedly tends to subdue, if not to kill, individuality. Where any pronounced originality exists, our whole effort should be to foster and develop it. I feel no doubt that the success of our university will entirely depend on the manner in which we allow room for individuality and originality in our courses, while the continued success of our college must depend on the freedom which we claim for individual teaching, even if in special cases the students should be kept out of the university altogether. Far better that a man of original mind should go through life without a degree, than that he should artificially be driven into the broad path of common-place reasoning. This country has never been wanting in men of the type I am speaking about; they are not brought up in the polytechnic schools of Germany, and never will be brought up by any schools formed on that pattern. Whatever success Germany has achieved is due to the stringent slavery of

its schools, followed and corrected by the absolute freedom of its universities.

I have spoken of two types of students, and the second is no less important than the first. The great majority of men are neither discoverers nor inventors, and they are for that very reason all the more in need of an education which will fit them for their life's work. It is in the instruction of this numerous class of students that we have most to learn, and it is in the intelligent organisation of their teaching that we are behind other countries. It has become a matter of vital importance for this college to offer a thorough training to those men, who, though they may not be leading spirits or original, yet form a necessary portion of the community and fill responsible positions in our industries. We have taken the first step to-day to remove one of the causes, which has hitherto prevented the physical department attracting these students in sufficient numbers. Our accommodation has till now been hopelessly deficient, but I hope that those who take the trouble to look through our plans will find that, as regards space and disposition of rooms, we may in future court comparison with any other institution. May I express the hope that the support which we shall get from our friends, will enable us to set the same of our equipment and instrumental appliances. I am, however, quite aware that building and equipment alone will not entirely solve the problem. Certain difficulties of instruction will have to be overcome, which will require not only the co-operation of different departments of the college, but also the help and advice of the manufacturers in whose workshops our students will have to complete their education. I attach the greatest importance to this help, and believe that real progress in what may be called the highest branch of technical education can only be secured by a frequent and sympathetic consultation between the teachers and employers of labour.

One further remark I should like to make in order to remove the objection which I know has been urged against our college, that we wish to unite in it students of different classes, and that, as in Germany, the university instruction should be entirely separated from that of the polytechnic school. But the separation of the two kinds of institutions in that country has not been chosen deliberately to secure the best educational result. It has been the consequence of the very high standard of classical education, which the universities require, and which it was not possible to enforce on the technical students. No one can urge that the literary requirements of our college or of our university are such as unjustly to exclude any one who is fitted to receive a higher technical education. If we want to find a country the educational institutions of which have grown unhampered by historical tradition, we must go to the United States of America, and amongst their universities we shall find some whose success we need not be afraid to emulate. I confess that no other institution has ever impressed me so much as regards efficiency in teaching organisation and completeness of laboratory organisation as the Cornell University at Ithaca. The class of students visiting that university are nearly akin to those we wish to attract, and if the citizens of Manchester could see the appliances of the physical laboratory and of its splendidly equipped dynamo house, I think we should have no difficulty here in obtaining the necessary funds for furnishing appropriately the rooms of our new laboratory.

The extraordinary development of electrical industries in the United States, and the great value which is in that country attached to a university education, may encourage us in the hope that the efforts we are making to extend and improve our electrical teaching will meet with some success.

I hope that the stress I have laid on our intentions regarding electro-technical teaching will not give rise to the impression that we mean to neglect other branches of physics. Our laboratory will provide arrangements for optical and more particularly spectroscopic work, which will at least be equal to that of any other institution; nor shall we forget the necessary machinery to produce very low temperatures by means of the liquefaction of air.

I had some hope originally to add a small astronomical observatory, but although the plans are such that it could be added at any time, the question of expense has for the present prevented us from carrying out a project for which there was no such pressing necessity.

THE INTERNATIONAL CONFERENCE ON SCIENTIFIC LITERATURE

THE official report of the proceedings of the second International Conference on Scientific Literature, recently held in the rooms of the Society of Antiquaries, the rooms of the Royal Society being under repair, is given below. The names of the delegates who attended the Conference have already been published in NATURE (p. 579).

ACTA.

OPENING MEETING, TUESDAY, OCTOBER 11

(1) Prof. Darboux moved that Sir John E. Gorst be the President of the Conference. The vote having been unanimously accepted—

(2) Sir John Gorst took the chair and welcomed the delegates. It was then resolved—

(3) That Prof. Armstrong be the Secretary for the English language.

That Prof. Korteweg be the Secretary for the German language.

That M. La Fontaine be the Secretary for the French language.

(4) That the Secretaries, with the help of shorthand reporters, be responsible for the *procès verbal* of the proceedings of the Conference in their respective languages.

(5) Prof. Foster read out the names of delegates appointed to attend the Conference, and gave an account of the correspondence relating to the non-representation of certain countries.

The following resolutions were then agreed to—

(6) That the ordinary hours of meeting be 11 a.m. to 1 p.m., and 4.30 to 4.45 p.m.

(7) That each delegate shall have a vote in deciding all questions brought before the Conference.

(8) That English, French, and German be the official languages of the Conference, but that it shall be open for any delegate to address the Conference in any other language, provided that he supplies for the *procès verbal* of the Conference a written translation of his remarks into one or other of the official languages.

(9) Prof. Foster having formally presented the Report of the Committee of the Royal Society, copies of which were forwarded, in April last, to the several Governments represented at the Conference, the discussion of the recommendations was opened, and it was resolved—

(10) That the Conference confirms the principle that the Catalogue be published in the double form of cards and book.

(11) That Schedules of Classification shall be authorised for the several branches of science which it is decided to include in the Catalogue.

(12) That geography be defined as limited to mathematical and physical geography, and that political and general geography be excluded.

(13) That anatomy be entered on the list as a separate subject.

(14) That a separate schedule be provided for each of the following branches of science.

Mathematics.	Palaentology
Anatomy.	Zoology.
Meteorology.	Botany.
Physics.	Physiology (including Pharmacology and Experimental Pathology).
Crystallography.	Bacteriology.
Chemistry.	Psychology.
Mineralogy.	Anthropology.
Geology (including Petrology).	
Geography—Mathematical and Physical.	

(15) That each of the sciences for which a separate schedule is provided shall be indicated by a symbol.

(16) Prof. Foster announced the reception of a letter from the German Chargé d'Affaires to the President of the Royal Society, stating that Geheimrath Reppertus-Eath Professor Dr. Klein, of Göttingen, had been appointed German Delegate to the Conference.

The regulations to be observed in the preparation of cards or slips were then taken into consideration, and it was resolved—

(17) That Italian should be added to the list of languages not requiring translation.

(18) That for each communication to be indexed at least one slip, to be called a *Primary Slip*, shall be prepared, on which shall be either printed or type-written or legibly hand-written in Roman script—

(i) *Title entries*.—The author's name and the full title of the communication, in the original language alone if the language be either English, French, German, Italian, or Latin.

In the case of other languages, the title shall be translated into English or such other of the above five languages as may be determined by the Collecting Bureau concerned; but in such case the original title shall be added, either in the original script, or transliterated into Roman script.

The title shall be followed by every necessary reference, including the year of publication, and such other symbols as may be determined. In the case of a separately published book, the place and year of publication, and the number of pages, &c., shall be given.

(ii) *Subject entries*, indicating as briefly as possible the principal subjects to which the communication refers. Every effort shall be made to restrict the number of these subject entries.

Such subject entries shall be given only in the original language of the communication if this be one of the five previously referred to, but in other cases in English or in such other language as has been used in translating the title.

[The Belgian delegates stated that they abstained from voting on the part of this resolution relating to subject-entries.]

SECOND MEETING, WEDNESDAY, OCTOBER 12.

(19) Prof. Korteweg having expressed the desire to be relieved of his office, it was resolved that Prof. Weiss be appointed Secretary for the German language.

The following resolutions were adopted—

(20) That the registration symbols used in the Catalogue be based on a convenient combined system of letters, numbers, or other symbols, adapted in the case of each branch of science to its individual needs, and in accordance, as far as possible, with a general system of registration.

(21) That the authoritative decision as to the Schedules be entrusted to an International Committee, to be hereafter nominated by this Conference.

(22) That the Conference is of opinion that the Delegates should be requested to take steps in their respective countries to organise local committees charged with the study of all questions relating to the International Catalogue of Scientific Literature, and to report within six months to the International Committee.

(23) That the International Committee (Resolution 22) be instructed to frame a Report, not later than July 31, 1899, which shall be issued by the Royal Society, and incorporated in the decisions of the Conference.

(24) That in all countries in which, or wherever, a Regional Bureau is established, as contemplated in the 16th Resolution of the International Conference of 1896, the Regional Bureau shall be responsible for the preparation (in accordance with Reg. 7 of the Royal Society's Report) of the slips requisite for indexing all the scientific literature of the region, whatever be the language in which that literature may appear.

That each Regional Bureau shall transmit such slips to the Central Bureau as rapidly and as frequently as may be found convenient.

That in the case of countries in which no Regional Bureau is established, the Central Bureau, failing other arrangements, shall, upon special mandate, endeavour to undertake the work of a Regional Bureau.

[The Belgian delegates stated that they abstained from voting on this resolution.]

(25) That the following recommendations of the Royal Society relating to the preparation of the Book Catalogue be referred to the International Committee for their favourable consideration, viz.—

"At determined regular intervals, not necessarily the same for all sciences, the Central Bureau shall compile from the slips and issue in a book form both an authors' and a subject index of the literature published within that period.

This Book Catalogue shall be obtainable in parts correspond-

ing to the several sciences for which slips are provided, and in such divisions of parts as may be hereafter determined.

In compiling the authors' index, in each of the sciences, the authors' names shall be arranged in alphabetical order, and each name shall be followed by the title of the paper and the necessary reference, and any other such symbols as may be determined.

The Book Subject Catalogue shall be compiled from the slips, as follows:—

- (i.) The subject entries shall be grouped in sections corresponding to the registration letters on the slips, *i.e.* to the several sciences.
- (ii.) In each science the several subject entries shall be arranged under headings corresponding to the registration numbers on the slips, the which headings and numbers shall be those contained in the authorised schedules of classification.
- (iii.) The divisions indicated by registration numbers may be further subdivided by means of significant words or symbols.
- (iv.) The nature of the subject entry may vary. Thus, as suggested in the cases of Mathematics and Physiology, it may be the title only; whilst in other sciences a special entry, more or less different from the title, may be provided on each slip. In all cases, the number of subject entries to be copied from a slip shall be determined by the number of registration numbers on the slip.
- (v.) The mode of arranging subject entries under a registration number, or under the subdivisions of a number afforded by significant words or symbols, may vary. They may either be arranged in the order of authors' names placed alphabetically, in which case the author's name shall precede the subject entry in the Book Catalogue, or they may be arranged either in an arbitrary order, or in some order suited to the particular series of entries.

When in preparing an issue of the Book Catalogue, it is found that a registration number has no entries collected under it, the number and corresponding heading may be omitted from that issue.

To each part of the Book Catalogue corresponding to an authorised schedule, there shall be appended an alphabetical index of the headings, and if expedient, also of the significant words appearing in that part, showing on which page of the part each may be found.

After the publication of the first issue of the Book Catalogue, the Director of the Central Bureau shall consult the Committees of Referees as to the desirability of making changes in the classification, and shall report thereon to the International Council, who shall have power to authorise such changes to be made as they may think expedient.

(26) That the following recommendations of the Royal Society providing for International Conventions in connection with the Catalogue be adopted:—

"Each region in which a Regional Bureau is established, charged with the duty of preparing and transmitting slips to the Central Bureau for the compilation of the Catalogue, shall be called a 'constituent region'."

In 1905, in 1910, and every tenth year afterwards, an International Convention shall be held in London (in July) to reconsider and, if necessary, revise the regulations for carrying out the work of the Catalogue authorised by the International Convention of 1898.

Such an International Convention shall consist of delegates appointed by the respective Governments to represent the constituent regions, but no region shall be represented by more than three delegates.

The rules of procedure of each International Convention shall be the same as those of the International Convention of 1898.

The decisions of an International Convention shall remain in force until the next Convention meets."

27. That the following recommendations of the Royal Society relating to the constitution of an International Council, which shall be the governing body of the Catalogue, be adopted:—

"Each Regional Bureau shall appoint one person to serve as a member of a body to be called *The International Council*."

The International Council shall, within the regulations laid down by the International Convention, be the Governing Body of the Catalogue.

The International Council shall appoint its own Chairman and Secretary.

It shall meet in London once in three years at least, and at such other times as the Chairman, with the concurrence of five other members, may specially appoint.

It shall, subject to the regulations laid down by the Convention, be the supreme authority for the consideration of and decision concerning all matters belonging to the Central Bureau. It shall make a report of its doings, and submit a balance sheet, copies of which shall be distributed to the several Regional Bureaux, and published in some recognised periodical or periodicals, in each of the constituent regions."

(28) That the following recommendations of the Royal Society relating to International Committees of Referees be referred for consideration to the International Council when constituted:—

"The International Council shall appoint for each science included in the Catalogue five persons skilled in that science, to form an International Committee of Referees, provided always that the Committees shall be as far as possible representative of the constituent regions. The members shall be appointed in such a way that one retires every year. Occasional vacancies shall be filled up by the Committee itself, subject to the approval of the Chairman of the International Council, and a member thus appointed shall hold office as long as the member whose place he fills would have held office."

It shall be the duty of the Director of the Central Bureau to consult the appropriate Committee or Committees, by correspondence or otherwise, on all questions of classification not provided for by the Catalogue Regulations; or, in cases of doubt, as to the meaning of those Regulations.

In any action touching classification the Director shall be guided by the written decision of a majority of the appropriate Committee, or by a minute if the Committee meets.

Provided always that when any addition to or change of the schedule of classification in any one branch may seem likely to affect the schedule of classification of some other branch or branches, the Committees concerned shall have been consulted; and provided also that in all cases of want of agreement within or between the Committees, or of other difficulty, the matter shall have been referred for decision to the International Council.

All business transacted by the Committees shall be reported by the Director to the International Council at their next ensuing meeting."

THIRD MEETING, THURSDAY, OCTOBER 13.

The following resolutions were adopted:—

(29) That the Committee contemplated in Resolution 21 be constituted as follows:—

Prof. Armstrong.	Prof. Poincaré.
Prof. Descamps.	Prof. Ricker.
Prof. M. Foster.	Prof. Waldeyer.
Dr S. P. Langley.	Prof. Weiss.

That this Committee be at liberty, if any of those named are unable to serve, to appoint substitutes, and also to co-opt two new members.

(30) That the International Committee be termed "*The Provisional International Committee*."

(31) That the Provisional International Committee shall be governed by the decisions of the Conference, but shall have the power of introducing such modifications in detail as may appear necessary.

(32) Dr Adler, referring to Resolution 20, said that he desired to place on record his view that the concluding words—"and in accordance, as far as possible, with a general system of registration"—the addition which he had agreed to as an amendment of his original Resolution, must not be regarded as modifying the first part of the Clause, or as in any way throwing open the whole question of notation and classification.

(33) Prof. Ricker having made a statement as to the probable cost of the undertaking, and the Delegates having stated what assistance in their opinion might be expected from their respective countries, it was resolved:—

That the Delegates to this Conference be requested to obtain information, and to report at an early date to the "*Provisional International Committee*," as to what assistance, by subscription or otherwise, towards the support of the Central Bureau, may be expected from their respective countries.

(34) M. Mascart called attention to Resolution 25 as being, in his opinion, incorrect in English, the intention being that the

local Committees therein referred to should report to the International Committee.

(35) The Royal Society was requested to undertake the editing, publication, and distribution of a verbatim report of the Proceedings of the Conference.

(36) It was resolved that the *procès verbal* of the Conference be signed by the President and Secretaries.

(37) On the motion of Prof. Armstrong, the thanks of the Conference were accorded to the Society of Antiquaries for the use of their rooms.

(38) On the motion of Prof. Klein, a vote of thanks to Sir John Gorst for presiding over the Conference and his conduct in the chair, was passed by acclamation.

(39) On the motion of M. Darboux a vote of thanks was passed to the Royal Society for their work in preparation for the Conference and their cordial reception of the Delegates.

(Signed)

NOTES

THE British Institute of Preventive Medicine, which was founded with the view of establishing in this country a national home for bacteriological work in all its branches has made considerable progress towards the achievement of this aim during the past few years. The bacteriological laboratories are now fully organised, the serum therapeutics laboratory is on a firm footing, whilst the applications of bacteriology to hygiene are finding full recognition. A further addition has just been made to the departments of the Institute in response to the growing demands of the times. A large laboratory at Chelsea has been assigned to investigation and instruction in technical bacteriology. In this laboratory the agriculturist, the chemist, the brewer, and others will find the instruction provided that they individually require for successfully employing the living agents of fermentation. Investigations will also be undertaken, and it is hoped that the laboratory will be a centre of useful work, and promote the advancement of a line of research of the greatest importance to the industries of the country. We have had hitherto to rely upon the research work of foreign laboratories in this direction. The laboratory has been named the Hansen laboratory, in recognition of the pioneer work of the distinguished investigator, and will be under the superintendence of Dr. G. Harris Morris. The formal opening of the British Institute will take place early in the new year, when the public will have an opportunity of inspecting the provisions made for furthering the objects of the Institute. The occasion will also be marked by the issue of a fresh volume of *Transactions* of the Institute, the first number of which was recently reviewed in these columns.

A LETTER signed "D Sc. (Lond.)," referring to a Science and Art Department's examination, appeared in NATURE of September 8 (p. 435), and in it the writer gave the following as an instance of anomalies which occur in examinations—"A student sat for the examination in May last in the advanced stage of practical organic chemistry. He was required to answer two questions, and to analyse two substances (unknown), as well as to find the halogen element present in an organic solid, and to determine the melting point of this solid. The written questions were correctly answered, the analyses were correctly done, the halogen was correctly determined, and the melting point of the substance was less than 1 per cent. too low. The description of the practical work was also fairly well done, but this student is returned as having failed, notwithstanding that there are two classes of success, first and second class. It would be interesting to know, in the face of this, the standard the examiners require for a first class success." Particulars which

enabled the examiner to again look at the paper worked by the candidate referred to were afterwards furnished us by "D Sc.," and the examiner now reports upon it as follows—"The written questions were partly answered, and on this part of the examination the candidate would have been allowed to pass, but the analyses were both very badly done, and the answers quite wrong. For the detection of the halogen and for the melting point he received the full marks awarded to this part of the work. It will be seen from this that the suggestion of an fair marking made by our correspondent is entirely without foundation. With regard to the other point referred to in the letter, we are sorry to say that 'D Sc.' would not furnish us with the name of the class in which he said that by the new rules the earnings this session will be reduced 75 per cent. We regret having unconsciously done an injustice to the Department of Science and Art by the publication of his letter.

THE following interesting announcement appears on a page in the catalogue of Messrs. Johnson, Matthey, and Co., Hatton Garden, London—"In furtherance of scientific research, Professors and recognised scientific investigators will with pleasure be supplied with metals of the platinum group, in moderate quantities and for periods to be arranged, free of charge, on condition that the precious metals are ultimately returned (in any form), and that the results of the investigations are furnished.

A PLEA for a national Antarctic expedition is made by Sir Clements Markham in a pamphlet published by the Royal Geographical Society. As was pointed out last week, in referring to the special Antarctic number of the *Scottish Geographical Magazine*, the only hope of maintaining the credit of our country in the work of exploration lies in an appeal to the patriotic feelings of those who possess the power which wealth supplies of providing the funds. The Council of the Royal Geographical Society generously offers to head the list with a subscription of 5000l. This example should be the means of showing that geographers are willing to help geographical discovery so far as their funds permit, and it also expresses their views upon the necessity of Antarctic exploration in an unmistakable form. It is earnestly to be hoped that the desire to enable the nation to retain its position as the first in exploration and discovery will inspire our wealthy countrymen to provide an amount equal to at least ten such subscriptions as that of the Royal Geographical Society. If this sum is not forthcoming, the prestige and credit won by former explorations will have to be resigned, and other nations will take our place as leaders in the work of geographical discovery.

AN attendant at the Pathological Institute attached to the Vienna General Hospital, died on October 18 from bubonic plague. It is believed that the man became infected by handling cultures of the plague bacillus. His duties were to look after the animals kept for the bacteriological study of the plague, but how he became infected has not yet been discovered. There is no doubt that the case was one of plague, an examination of the sputum having revealed the presence of the plague bacillus. Since the assistant's death Dr. Müller, who attended him, has also died from the plague, and a nurse infected by it is described as in a condition which leaves little hope of recovery.

THE *Times* correspondent at Copenhagen announces that an international monument in honour of the famous Danish physician, Dr. Hans Wilhelm Meyer, who died three years ago, was unveiled in that city on Tuesday. Dr. Meyer was the discoverer of what are called adenoid growths. He found that the space between the nose and the throat, which ordinarily is an open cavity, is in certain persons suffering from adenoids more or less closed by a large, soft mass. He found that this mass in

numerous cases causes lifelong deafness, obstructs nasal respiration, and greatly retards the mental development of the patients, who are generally young. He succeeded in removing these growths by operation. Shortly before his death his discovery was universally recognised as being of the utmost importance. The monument has been erected by International subscriptions, committees having been formed in almost every civilised country, and not only members of the medical profession but also grateful patients contributing. The memorial is a bronze bust of more than life size, resting upon a granite base. In front stands a figure of Hygieia, beneath which is inscribed the name "Hans Wilhelm Meyer." On the other side may be read the names of all the countries which have contributed to the memorial. The monument is the work of the Danish artists Bissen and Runeberg.

THE death is announced of Dr. Eugenio Bettoni, director of the Fisheries Station at Brescia, at the age of fifty-three years.

SIR JOHN MURRAY, F.R.S., has resigned the post of scientific member of the Fishery Board for Scotland, to which he was appointed by the Crown in January 1896.

THE opening meeting of the new session of the Institution of Electrical Engineers will be held on Thursday, November 10, when a paper will be read by Prof. Silvanus P. Thompson on "Rotatory Transformers." The annual dinner will take place in the Grand Hall of the Hôtel Cecil on Wednesday, December 7.

A DISPATCH describing a series of attempts to climb Mount Sorata, or Illampu, in the Eastern cordillera of the Andes of Bolivia, has been sent to the *Daily Chronicle* by Sir Martin Conway. The highest point attained was well over 23,000 feet, and probably as much as 24,000 feet, but the summit was not reached.

We learn from *Science* that the U.S. Fish Commissioner has presented to Cornell University a collection of fresh water and salt-water fishes, numbering between four and five hundred thousand specimens. The collection, in so far as it consists of living fishes, will be of great value not only to the zoological department, but also to the College of Forestry, in which a course in pisciculture and venery is to be introduced. It is understood that duplicates of this collection are to be presented to other institutions.

THE existence of a number of species of silk-spinning worms in the Sewaliks and Himalayas, and the extensive use of silk as a material for dress, make the question of sericulture in India a matter of great interest. The *Pioneer Mail* of October 7 prints an account of three different sets of experiments in progress during the current year in the North Western Provinces to establish silkworm rearing—one in the plains, another in the Dun Valley, and the third on the Himalayas. All were carried out under different conditions of temperature, and all achieved a degree of success that is encouraging.

THE *Athenaeum* announces that Don Francisco Coello de Portugal, who occupied in Spain the foremost rank as a geographer, has just died at Madrid at an advanced age. He had originally embraced the military career, and after having quitted the army in 1865 with the rank of colonel, he devoted himself chiefly to the science of geography, and published an excellent "Atlas of Spain and its Colonies," which will now, of course, be out of date. He was president of the Geographical Society of Madrid, and frequently represented Spain as delegate at scientific congresses.

A CORRESPONDENT sends us a letter he has received from Ballyathana in the Vale of Ovoca, County Wicklow, with reference

to a curious object observed in the sky on Wednesday evening, October 19, about six o'clock. The object was visible in the south-west, and looked like a three-quarter moon. It was moving gradually from south-east to north-west, and appeared to the observer to go down behind the Croghan Kinalea mountain. It was of a golden colour, and was seen for four or five minutes. The suggestion is made that the object was a meteor, but it may have been merely an escaped balloon. Perhaps it was seen by other observers in Wicklow, or Wexford, who could give further particulars concerning it.

We learn from the *British Medical Journal* that it has been determined to appoint a special commission, to consist of five members, to conduct investigations regarding plague in India. The specific duty of the commission will be to inquire into the origin of the various outbreaks of plague, and the manner in which the disease is spread. An official statement also is required as to the efficacy of the serum treatment and the prevention of plague by means of inoculation. So far as the nominations to serve on this commission have been made public two Indian civilians, Messrs. J. R. Sewett and A. Cumie, have already been appointed, but it is understood that three other members will be nominated by the Secretary of State for India, to proceed from this country, of whom one will act as chairman, while two will be experts.

PARTICULARS concerning the expedition which will leave England in the course of the next few days for the purpose of visiting the almost unexplored island of Sokotra, situated about 150 miles east north-east of Cape Guardafui, are given in Tuesday's *Times*. The party will consist of Mr. W. R. Ogilvie Grant, of the department of zoology in the British Museum; Dr. H. O. Forbes, the director of the Liverpool Museum; and Mr. Cutmore, taxidermist attached to the latter institution. The Royal Society, the Royal Geographical Society, and the British Association have provided part of the funds for the undertaking. The expedition will sail for Aden, proceeding thence to Sokotra by the Indian Marine guardship *Epiphronia*, which, in compliance with a request made by the authorities of the British Museum, has been kindly placed at the disposal of Mr. Grant and Dr. Forbes for the purpose of conveying them to the island and back to Aden on the termination of their stay. The main object of the expedition is to investigate thoroughly the fauna of the place and make large and complete collections in every branch of zoology.

THE space to be devoted to the various sections of the Paris Exposition of 1900 has been arranged by the Commissioner-General as follows—

Agricultural and food products	84 ft.
Army and navy	20,000
Chemical industries	3,300
Education, instruments, practical sciences, and arts	5,160
Fine arts	11,470
Forestry, hunting and fisheries	(not yet known)
Heating apparatus	3,300
Horticulture	4,500
Machinery and electricity	(not yet known)
Manufactures	50,000
Mines and mining	25,000
Textiles	7,700
Transportation and civil engineering	13,000
Total	20,000
	163,430

IT is of great importance that those who are engaged in archaeological research should be properly trained; therefore the British School at Athens by supplying the needful training is doing very valuable work. This was the text of the remarks made by the Bishop of London at the annual meeting of the

School, held on Thursday last. Referring to the excavations at the prehistoric capital of the island of Melos, discovered at Phylakopi, the director of the School, Mr. Hogarth, said that the School began to excavate it in 1896, little suspecting the great importance of the site. It was proving a second Hisarlik, an undisturbed repository of the products of the primitive civilisation of the Aegean from the "Mycenean" age back to the Neolithic period. Much had been eaten away by the sea, but what was left was equal in extent to Troy. Mr. Hogarth picked up the work where Mr. Cecil Smith left it, and after determining the limits of the city on south and east, and digging test trenches to obtain a relative chronology of the potsherds, in which the site was marvellously rich, proceeded to open out the great barrack-like structures on the north and west. Here were remains of three settlements, divided by layers of debris, the middle and lower ones being singularly well preserved. The best rooms were on the higher ground to the west. The blocks were divided by narrow lanes with covered drains down the centre. The depth varied from seven metres to three metres. In the two lower settlements was found a mass of pottery, and almost as many vessels, complete or little broken, as in a large cemetery. These covered the whole development of the potters' art up to the fine Mycenaean work. Fabrics, shapes, and decoration were in many cases new. The most notable vase was pipe-shaped and decorated with four scantily-clad figures, bearing fish in either hand. This was about the most interesting primitive Aegean vase in existence. In several rooms painted fresco was found, in one case white and gold lines on a red ground; in another a beautiful scene of the sea with flying fish and marine growths, and a man working a casting net. Of the primitive symbols now attracting so much attention on Cretan stones, &c., over fifty distinct examples were found scratched in clay before baking. Many fine stoneware vases, clay lamps (unknown previously on early sites), and other stone utensils and implements came to light. There was a little bronze and bone, but no gold or silver.

REFERRING to the collection of mollusca in the Madras Government Museum, Mr. Edgar Thurston states, in his report for the year 1897-98, that a right-handed chank shell (*Turbinella raphe*), that is, a chank shell with its spiral opening to the right, was acquired in the Madras bazaar for the small sum of Rs. 150. A shell of this nature, found off the coast of Ceylon at Jaffna in 1887, was sold for Rs. 700. Such a chank is said to have been sometimes priced at a lakh of rupees (Rs. 1,00,000); and, writing in 1813, Milburn says ("Oriental Commerce") that a chank opening to the right hand is highly valued, and always sells for its weight in gold. Further, Baldaus, writing towards the close of the seventeenth century, narrates the legend that Garroude (Garuda) flew in all haste to Brahma, and brought to Krishna the chanko or kink-horn twisted to the right.

It has been suggested by several people that the recent wreck of the *Mohagan* on the Manacles Rocks was due to a local deviation of the compass of the ship. In a letter to the *Times*, Prof. A. W. Rüchler points out that a disturbance of a magnitude sufficient to have caused the disaster is most improbable. He remarks:—"During the magnetic survey of the United Kingdom, carried out by Dr. Thorpe and myself, observations were made at twelve places in Cornwall. Of these Lizard Down, Porthallow, and Falmouth were the nearest to the scene of the disaster, and at all of them the deviation of the compass from the normal magnetic meridian was extremely small. The largest disturbance of this kind which was observed in Cornwall occurred at St. Levan, near the Land's End, and only amounted to eleven minutes of arc, or less than two-tenths of a degree. The largest disturbance of the dipping needle was at Mullion, and was only fourteen minutes."

NO. 1513, VOL. 58]

MR. F. H. GLEW, of 156 Clapham Road, sends us a photograph of an oscillatory electric discharge which was taken in daylight. The photographic shutter was connected with a coherer and relay, so that the first component of the discharge operated the shutter and allowed an image of the succeeding components of the discharge to be caught. Mr. Glew suggests that a similar arrangement might be employed for photographing lightning in the day-time. Mr. Glew also sends us a photograph of a flash of lightning taken with a vibrating lens. From the multiple image produced, and the rate of vibration, he calculates that the total duration of the flash in question, which appears to have been of a triple compound nature, was one-nineteenth of a second, or less than one-half of a single vibration of the lens. He has also used a rotating photographic plate, but finds the vibrating lens to be more satisfactory.

Two papers on the circulation of the residual gaseous matter in Crookes' tubes, read before the Physical Society by Mr. A. A. C. Swinton, appear in the October number of the *Philosophical Magazine*. The experiments described lead to the conclusion that "at very high exhaustions there exists a molecular or atomic stream from anode to cathode, which carries a positive charge and travels at considerable velocity outside of the opposite cathode-stream."

WHEN the poles of an arbitrary plane are taken, with respect to the cones of a Steiner's surface, it is known that another Steiner's surface is obtained. Prof. Brambilla, writing in the *Rendiconto* of the Naples Academy, IV, 7, has extended the same property to the two non-ruled surfaces of the fourth order, one in four-dimensional and the other in five-dimensional space, which, when projected from one or two arbitrary centres on our space, produce Steiner's surfaces.

THE phenomenon of equilibrium in mixtures of isomorphous substances has been studied by Küster since 1890. A further investigation, leading to somewhat different conclusions, is given by Signor Giuseppe Bruni in the *Atti dei Lincei*, vii, 5, who finds that the curve of congelation of a mixture deviates to a marked extent from the straight line obtained by Küster, and that serious objections can be raised against the latter's views on the coefficient of distribution. Signor Bruni, however, concludes that, in respect both of the variations in the temperature of congelation and of the distribution of the solid and liquid phases, isomorphous mixtures always follow completely the general theory of Van 't Hoff on solid solutions.

A SOMEWHAT novel line of investigation, which bids fair to throw light on certain problems of petrology, has been taken up by Prof. R. V. Matteucci in connection with the last eruption of Vesuvius. The method consists in artificially cooling portions of flowing lava, so as to partially or totally check the crystallisation of the substances contained in their magma; and in this way it appears possible to obtain information as to the exact stages at which different minerals separate out from the first exit of the lava up to its final consolidation.

THE coasts of Japan are peculiarly liable to incursions from spring tides, of which the one occurring on June 15, 1896, in the course of eighteen minutes swept away 9381 houses and 6930 boats, killing 21,909 people and wounding 4398. To minimise the damage done to life and property by such inroads, protective forests have been planted at various places along the littoral. Dr. Seiroku Honda, Professor of Forestry in the University of Tokyo, writing in the *Bulletin* of the Imperial University College of Agriculture, gives an interesting account of these protective forests, and advocates their further extension to parts as yet unprotected. The action of these forests is threefold: they check the force of the tidal wave; they delay its

advance, giving more time for saving the lives of inhabitants living behind the forest; and, lastly, they prevent houses and property from being washed away into the sea. Dr Honda gives a list of the trees which are best adapted for this purpose.—In the same number of the *Bulletin* Dr. Diro Kitao, by the use of the equations of elasticity, has endeavoured to reduce the calculation of the shrinkage and swelling of wood to mathematical principles.

THE interpretation of death among the lower organisms is ably dealt with by Signor Angelo Andres in the *Rendiconto del R. Istituto Lombardo*, xxxi. 13. The author, after pointing out the objections to Weismann's views, starts with the conception that living organic matter does not in itself possess any reason for dying, and that, on the other hand, this reason pertains to single individuals, in other words, that living matter remains in itself immortal, and that only the modality of the individual dies. An examination of the lowest forms of algae leads Signor Andres to the conclusion that the first indications of true death occur in the Diatomeae, in which the process of subdivision leads to a gradual diminution in the size of the frustules, as also in the Volvocine, where the phenomenon of death is still more marked. The cause of death, it would appear, is to be sought in the differentiation which, by the specialisation of structure and function, leads to the perfecting, both anatomically and physiologically, of different species.

THE *Engineering Magazine* for September contains an article on the bacterial process of sewage purification, which is at the present time attracting a considerable amount of attention; and is under investigation by a Commission appointed by the Local Government Board. The purification of sewage is a process of destruction of the organic matter by means of bacteria, and finally of the bacteria themselves from manure. These bacteria are divided into two classes—*aerobic*, which require oxygen for their growth, and do their work best when sewage is exposed to the air, and the *anaerobic*, which do not require oxygen for their growth, and do their work best in the dark. The former process of purification has been in use in this country for some years, having been first adopted by Mr. Bailey Denton in the system known as intermittent filtration through beds of earth. The latter system is of more recent origin, and has only been prominently before the public since the septic system was adopted by Mr. Cameron, the Borough Surveyor at Exeter. Besides the works at Exeter, others are in operation at Sutton and Yeovil, all of which are described and illustrated in the article by Mr. Rudolph Hering.

A SHORT account of the various steps that have been taken in the acclimatisation of trout in South Africa is given by Mr. J. D. F. Gilchrist in his report of 1897 on the sea and inland fisheries of Cape Colony. So far back as 1884, Mr. Lachlan Maclean began the experiment of trout acclimatisation in the Colony by importing 20,000 ova; and in spite of various difficulties and failures he proved its practicability. His experiments showed that the rearing of trout from imported eggs was feasible, and it is due to his success that the rivers are now being gradually stocked with valuable fish. The Cape Government took up the subject in 1890, and about a year later a hundred thousand trout ova were procured from Guildford, Surrey, a large number of which were hatched successfully. The work has since been carried on by the Cape Agricultural Department, and has undergone a steady progressive development. The trout turned into the rivers thrive exceedingly well, and many of them attain a large size.

AMONG other matters mentioned in the Report of the Marine Biologist referred to in the foregoing note, are trawling experiments performed with a view to introduce new and improved

methods of fishing. It has been demonstrated that there is an excellent trawling ground rivaling the North Sea in productiveness, within easy reach of Cape Town. A satisfactory feature of the work is the discovery that soles occur abundantly on the fishing grounds, and can be readily got by trawling. As a scientific result of the experiments it may be mentioned that six different kinds of flat fish, one of which is new to science, have been discovered. The subject of temperatures, currents, &c., of the sea in relation to the scientific side of fishing investigations is being taken up; and Mr. Gilchrist announces that arrangements have been made at about a dozen different places for physical observations of this kind to be carried on.

THE latest number of *Jahrbuch*, a journal which is open to contributors from all parts of the world in divers tongues on subjects relating to the history of medicine and medical geography, contains an interesting and well-written article on medical archaeology dealing with the significance of the plant Silphium and its therapeutic value amongst the ancients. Dr. Kronfeld of Vienna is the writer, and he has illustrated his article by a reproduction of the well-known dish of Arkesilas, now in the "Cabinet des Médailles" of the National Library in Paris. Graphic and very realistic scenes are depicted indicating the immense store set by the ancient Greeks upon this remarkable plant, whose habitat was located in Cyrene. Its applications seem to have been as diverse as they were valuable, and amongst its numerous uses we find it treasured as furnishing the earliest and most delicate of vegetables, also spice, whilst its therapeutic reputation was almost as universal as that claimed for some of our modern nostrums by their inventors! Silphium has long since disappeared from Cyrene, but Falconer has found in the northern parts of Cashmere a plant which is regarded as being very closely allied to its historic predecessor.

THE Geological Survey has just published a brief Supplement to the Memoir on the Geology of Flint, Mold, and Ruthin, by Mr. A. Strahan. This Supplement contains records of borings put down in the reclaimed portion of the estuary of the Dee; and these are of importance as proving the presence of Upper Coal-measures, which do not appear at the surface and were not previously known to exist in Flintshire or West Cheshire. In this region the Middle Coal-measures are the productive strata, and the new information shows that the Upper Coal-measures may underlie much or all of the Cheshire Trias, and would consequently have to be penetrated in winning the coal. The price of the Supplement is 2d.

In the *Journal of Applied Microscopy* (Bausch and Lomb) for August is a description of the Histological Laboratory of the Harvard University at Washington, D.C.

WE have received part 4 of vol. xxv. of Engler's *Botanische Jahrbücher*, occupied chiefly by a continuation of Pittier's review of the classification of Orchideae, and the commencement of a systematic paper on the Monimiaceae by J. R. Perkins.

WE have received the Reports of the Botanical Exchange Club for 1896 and 1897, both bearing the date 1898, the latter edited by Mr. G. Claridge Druce. They are both occupied by a record of new British localities, and by remarks on "critical" British species. The discovery is recorded of a new British sedge, *Carex chordearia*.

In the *Revue Générale des Sciences* for September, M. L. Mangin has a short article on the sexuality of Fungi, in which he shows the remarkable advance that has been made during recent years in the discovery of sexual organs in various classes of Fungi. Especial reference is made to the *resporobes* of Harper on the Ascomycetes, of Dangeard on the *microspores* of Fungi, of Sappin-Troffon on the Uredines, and of Thaxter on the Laboulbeniaceae.

THE *Journal* of the Royal Microscopical Society for October contains a continuation of Mr. F. W. Millett's report on the recent Foraminifera of the Malay Archipelago collected by Mr. A. Dornand, and the usual summary of current researches in zoology, botany, and microscopy. Among the latter is an abstract of Mr. Lewis Wright's important paper on microscopic images and vision.

THE *Biologische Centralblatt* continues its useful summaries of recent researches in vegetable biology and physiology. In the numbers for September 15 and October 1 are contributions by Dr. R. Keller on the nyctitropic movements of leaves; on the mechanical action of rain on plants; on the flexibility of axial organs, and their capacity for resisting strain; on the comparative intensity of assimilation in plants in the Tropics and in Central Europe; and on the freezing of plants.

THE *Naturwissenschaftliche Wochenschrift* for October 2 contains an interesting paper by F. Schlechter, being a report of observations on several points of vegetable physiology. He finds that the highest temperature in the interior of a stem (12 cm. depth from the surface) occurs about midnight, the lowest between noon and 3 p.m. While the chief factor which governs the temperature of the interior of a tree is the temperature of the surrounding air (about twelve hours earlier), it is also affected by the temperature of the soil, by that of the ascending current of water, and by the degree to which the twigs are exposed to direct sunlight.

THE papers read at the third annual congress of the South-Eastern Union of Scientific Societies, held at Croydon in June, are printed in the *Report and Transactions* just published by Messrs. Taylor and Francis. Among the subjects of the papers are: The place of geology in education, entomology as a scientific pursuit; the nature of the soil in relation to the distribution of plants and animals; natural gas in Sussex; photography in relation to science, ideals for natural history societies, and how to attain them; and the folk-lore of amulets and charms. The volume thus contains information of interest and value to the members of all natural history societies.

FROM the United States we have received the following official publications:—"Principal Poisonous Plants of the United States," by V. K. Chesnut (U.S. Department of Agriculture *Bulletin* No. 20); a very useful publication, but the illustrations to which might be improved; we should hardly have recognised two of the imported European weeds, *Solanum nigrum* and *Conium maculatum*. Sixth Report on Kansas weeds (*Bulletin* No. 30, Experiment Station of the Kansas State Agricultural College, Manhattan); in this, and in other similar American publications, we note the introduction of the practice of noting graphically, by small maps, the distribution of the various species throughout the different States.

THERE is an interesting paper in the *American Naturalist* for September on some European museums, especially from a geological and mineralogical point of view, by Mr. E. O. Hovey. The small "Roemer Museum" at the quaint medieval city of Hildesheim, near Hanover, is especially commended. Those visited by the writer in Russia presented no particular features of interest, the value of the magnificent collection of minerals in the Imperial Mining Institute at St. Petersburg being greatly marred by a faulty arrangement. Brief accounts are also given of the Natural History Museum at Berlin; the University Museum at Naples; the Museum of Natural History at the University of Geneva; the collection of minerals at the Jardin des Plantes, and the splendid collection of the École des Mines, Paris; the Museum of Practical Geology in Jermyn Street, London, and the collection at the British Museum; and the Woodwardian Museum, Cambridge.

MR. W. S. BLATCHLEY, State Geologist of Indiana, has issued his report (occupying 1197 pages) on the work accomplished by the department of geology and natural resources during the year 1897. A large proportion of the energies of the department were employed during that year in collecting data for a detailed report on the coal area of the State, shortly to be published. The present report includes papers of economic importance relating to petroleum, stone and clay resources of the State, the reports of the chiefs of the divisions pertaining to mines, natural gas and illuminating oils, and a long descriptive illustrated catalogue (666 pp.), by Mr. A. W. Butler, on the birds which have been observed within the State of Indiana, with an account of their habits.

A SECOND English edition of Prof. von Meyer's well known "History of Chemistry from the Earliest Times to the Present Day" has just been published by Messrs. Macmillan and Co., Ltd. The first English edition, translated from the original German edition by Dr. George McGowan, appeared in 1891. Dr. McGowan is alike responsible for the present volume, which is translated from the second German edition, with numerous additions and alterations. It is unnecessary to refer here to the value of the work, or to add to the account of it given in our review of the English version (*NATURE*, vol. xlv p. 289). It is sufficient to say that in the second edition, published in 1895, Prof. von Meyer made use of all the additional sources of information on subjects of historical chemistry which had become available since the original work was written. "Among these," Dr. McGowan remarks, "are the Berzelius Liebig and the Liebig Wohler letters, the Letters and Journals of Scheele, Priestley's Letters, and the autobiographical fragment which Liebig left behind him. In addition, there are the recently published and valuable historical researches of Berthelot on the chemistry of the early Middle Ages, and the writings of Ladenburg, Schorlemmer, Thorpe, Girmaux, and others on the development of chemistry within certain definite periods, or on the life and work of particular chemists." These additions add to the value of what has always been a volume of great interest to students of chemistry, and we do not doubt that the new edition will be even more successful than the former one.

THE additions to the Zoological Society's Gardens during the past week include a Siamese (*Hylobates syndactylus*) from Sumatra, a Thick-necked Terrapin (*Bella crassicollis*), a Siamese Terrapin (*Danionia subtrynga*), a Burmese Tortoise (*Testudo elongata*) from Siam, an Ambonia Box Tortoise (*Cyclanina ambonensis*) from Borneo, presented by Mr. Stanley S. Flower; a Negro Tamarin (*Mydas ursinus*) from Guiana, presented by Mr. E. F. Brooker; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Miss Abchurch; a Pig-tailed Monkey (*Macacus nemistinus*) from the East Indies, presented by Mr. R. O. Bell; a Common Paradoxure (*Paradoxurus niger*) from India, presented by Mr. H. A. Cottrell; two Capybaras (*Hydrochares capybara*) from South America, presented by Mr. Basil J. Freeland; a short-winged Weaver-bird (*Hyphantornis brachyptera*) from South Africa, presented by Miss Alice Heale; an Emu (*Dromaeus nova hollandia*) from Australia, presented by Sir Cuthbert Peek, Bart.; a Suncate (*Suricata tetradactyla*) from South Africa, presented by Miss Peek; two Starred Tortoises (*Testudo elegans*) from India, presented by Mr. J. Freeman; a Smooth-headed Capuchin (*Cebus monachus*) from South-east Brazil, a Rabbit-eared Bandicoot (*Peragale lagotis*) from Western Australia, a Vulpine Phalanger (*Trichosurus vulpecula*) from Australia, deposited; six Mate Swans (*Cygnus olor*) from Holland, purchased; two Rose-faced Love-birds (*Agapornis roseicollis*), bred in the Menagerie.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN NOVEMBER.—

- November 1 5h. 17m. to 6h. om. Occultation of 103 Tauri (mag. 5.5) by the moon
5. 4h. Mars 3° 41' N. of the moon.
- 12 Mars rises at 9h. and visible afterwards through out the night in Cancer. Diameter of the planet 5".6.
15. Mars Illuminated portion of disc = 0.900.
15. Jupiter becomes visible as a morning star Polar diameter 28".8
15. Meteoric shower from Leo in the early morning hours. (Radiant 149° + 23°.)
16. 7h. Vesta 10' N. of the moon
17. 10h 11m Minimum of Algol (β Persei).
20. 7h Minimum of Algol (β Persei)
- 22 7h 9m to 8h. 13m Occultation of 19 Piscium (mag. 5.2) by the moon
- 23-24. Meteoric shower from Biela's comet (Radiant 25° + 43°.)
- 25 12h Uranus in conjunction with the sun
- 28 14h 7m to 15h 6m Occultation of 103 Tauri (mag. 5.5) by the moon
29. 11h 19m to 11h 49m. Occultation of the star DM + 24°, 1033 (mag. 6.0) by the moon.

COMET BROOKS.—A telegram from Kiel, dated October 21, informs us that at 7h Geneva time, on October 20, Brooks found a comet in position R A 14h 32m 8s and Decl + 60° 26'. It was moving in a south easterly direction, and was described as "bright." A later telegram, dated October 22, gives the position of the comet from an observation made at Pola on October 21, at 16h. 48.5m. Pola mean time, this was R A 15h 4m 12s and Decl + 57° 50'.

The comet was thus situated in the constellation of Draco, and moving to the south of the star β Draconis.

THE LARGE SUN-SPOT.—In this column for September 8 we drew attention to the large spot that had a few days previously made its appearance on the eastern limb of the sun, and remarked that "the spot will be well worth watching during the remaining period of its visibility, especially as many years may perhaps elapse before observers are favoured with another spot of similar size."

At the present time there is another great spot, larger, perhaps, than the one referred to above, which is now beautifully visible near the centre of the solar disc. This very compact group, which is not situated very far from the solar equator, is composed of two large umbrae surrounded by rather irregular shaped penumbrae, with several small spots scattered around them. Another smaller spot is also following the large one.

It will be well for observers to look out for an aurora and magnetic storm when the spot passes the central meridian, as was the case when the spot, previously referred to, was in the same position on September 9 last.

THE HARVARD ASTROPHYSICAL CONFERENCE.—It was on the occasion of the dedication of the Yerkes Observatory that the Americans held their first astrophysical conference. So great was the success of this, their first trial, that it was expected that more would be held in after years. For this we had not long to wait, and we have now before us a full account of the conference recently held at Harvard, the oldest observatory devoted to astrophysical research, contributed to *Science* (October 7) from the pen of Prof. M. B. Snyder. There could have been no more appropriate place of meeting in America for the second conference than that of the Harvard College Observatory, for Prof. E. C. Pickering's vast organisation of work in all modern branches of astronomy is second to none.

The conference was presided over alternately by Prof. J. R. Eastman, of the United States Naval Observatory, and Prof. Hale, of the Yerkes Observatory, and the meetings were not only held on August 18, 19 and 20, but were carried over to a series of adjourned meetings held during the course of the subsequent week.

The papers read were very numerous, and dealt with all kinds of astrophysical work. The work carried on at Harvard formed, perhaps, the chief item in the programme. Some of the papers dealt with were as follows:—

1. Prof. George Comstock, on "Some Investigations relating to zenith telescope latitudes"; Dr. Harold Jacoby, on "Photo-

graphic researches near the pole of the Heavens"; Mrs. Fleming, on "Stars of the fifth type in the Magellanic clouds," which establishes another connection between these objects and the Milky Way.

Prof. Solon Bailey presented a paper on "Variable stars in clusters," which is a subject most interesting in the light of recent investigations.

We notice that general plans for observing the total eclipse of the sun on May 28, 1900, were briefly discussed, and a committee appointed to consider the work of organisation.

Another important question brought up at the conference was the creation of a permanent astronomical and astrophysical society. This proposal was formally accepted, and a committee, consisting of Profs. Hale, Comstock, Pickering, Newcomb and Morley, was appointed to consider the organisation.

THE KNIGHT-DARWIN LAW¹

THE law under the above title is known to botanists through H. Muller ("Befruchtung der Blumen," Eng. trans., p. 4), who says that Andrew Knight "laid down the law that in no plant does self fertilisation occur for an unlimited number of generations." This he calls the Knight's Law, and later, in substantially the same form, it becomes the Knight-Darwin Law. For the statement of Knight's Law the reader is referred to that author's celebrated paper "An account of some experiments on the fecundation of vegetables" (Phil. Trans., 1799). The words, however, do not occur in Knight's paper, and I imagine that Muller got them from Charles Darwin's paper on the fertilisation of papilionaceous flowers, where occurs the passage (*Gardener's Chronicle*, 1858) "Andrew Knight many years ago propounded the doctrine that no plant self-fertilises itself for a perpetuity of generations."² The words are not given in inverted commas, and I strongly suspect that, with a singular lapse of his usual accuracy, my father was merely giving his own interpretation of the conclusion which seemed to flow from Knight's expressions when taken with the whole of the context. For in the "Effects of Cross- and Self-fertilisation," 1796, p. 7, he quotes Knight's actual words. After referring to Sprengel, he goes on "Andrew Knight saw the truth much more clearly, for he remarks 'Nature intended that a sexual intercourse should take place between neighbouring plants of the same species' . . . and again 'Nature has something more in view than that its own proper males should fecundate each blossom.' Here we have simply the general statement that hermaphrodite flowers are not necessarily self-fertilised, a statement of fundamental importance in floral biology. If the positive statement that 'no plant self-fertilises itself for a perpetuity of generations' is to be found elsewhere in Knight's writings, I think Darwin would have quoted it.

In the "Origin of Species" (edition 1, p. 96) he refers to Knight in the following words "Nevertheless I am strongly inclined to believe that with all hermaphrodites two individuals, either occasionally or habitually, concur for the reproduction of their kind. This view, I may add, was first suggested by Andrew Knight."

Lastly, in 1868 ("Variation of Animals and Plants," ii p. 175), after speaking of his own hypothesis, "that it is a law of nature that organic beings shall not fertilise themselves for perpetuity," he adds "This law was first plainly hinted at in 1799, with respect to plants, by Andrew Knight." If he had known any positive expressions—going beyond the nature of a hint—in Knight's writings, would he not have quoted them? It seems, therefore, that, as far as Knight is concerned, the law should be a general statement of the tendency to cross-fertilisation of hermaphrodites, and not the positive statement quoted by Muller.

When we pass from Knight's share in the law to Charles Darwin's—there are difficulties in fixing on the most authentic wording of the law. The earliest form is that occurring in the "Origin of Species" (ed. 1, p. 97)

"These facts alone incline me to believe that it is a general law of nature (utterly ignorant though we be of the meaning of the law) that no organic being self-fertilises itself for an eternity of generations; but that it crosses with another individual occasionally—perhaps at very long intervals—indispensable."

In the sixth edition of the "Origin," 1872, he retains the above passage with the omission of the words "(utterly

¹ A paper read before Section K (Botany) at the British Association, 1898.

² This sentence is quoted by Muller, "Historical Introduction," p. 40.

ignorant though we be . . . law," and with the addition of a reference to his own experiments, *i.e.* to those on cross-fertilisation.

This is the most strongly worded form of the Law, and one which is generally acknowledged. But shortly after the publication of the "Origin," *i.e.* in 1862, the Law took a vaguer form in the "Fertilisation of Orchids" (ed. 1, 1862, p. 359), where he wrote: "Nature thus tells us, in the most emphatic manner, that she abhors perpetual self-fertilisation." This form of the Law is adopted in the "Effects of Cross- and Self-fertilisation" (p. 8), where he writes: "If the word perpetual had been omitted, the aphorism would have been false. As it stands, I believe that it is true, though perhaps rather too strongly expressed."

The aphorism is clearly not a literal statement of fact, and in describing it as "true," he probably meant that perpetual self-fertilisation is very strongly and very generally guarded against in nature. For he well knew that "some few plants seem to be invariably self-fertilised" ("Cross- and Self-Fertilisation," p. 3). With regard to these cases he makes the just remark: "These exceptions need not make us doubt the truth of the above rule, any more than the existence of some few plants which produce flowers, and yet never set seed, should make us doubt that flowers are adapted for the production of seed and the propagation of the species."

It is only fair to add that this argument also occurs in the "Variation of Animals and Plants under Domestication" (vol. II, p. 91, 1868), and was therefore of considerably earlier date than his book on "Cross- and Self-Fertilisation" (1876).

To sum up

(1) If the expression, Knight-Darwin Law, is to continue in use, it ought to be applied to a statement on which Knight and Darwin are undoubtedly agreed, *i.e.* that "nature intended that a sexual intercourse should take place between neighbouring plants of the same species."

But the name of Knight-Darwin Law is now firmly associated with the positive statement "that no organic being fertilises itself for an eternity of generations," and it would be useless to suggest a new nomenclature.

(2) If we are to take a Darwinian version of the Law, it seems to me fatter to take the term, "nature abhors perpetual self-fertilisation," which my father adhered to in his later books.

An example of what seems to me the misuse of the Knight-Darwin Law occurs in my friend Mr Willis' excellent book, "Flowering Plants and Ferns" (vol. I, p. 46). "In *Myrmecodia*, &c., Burck has found crossing absolutely prevented, the flowers never opening. Hence the Knight Darwin hypothesis must be abandoned." If the abandonment of the hypothesis means the recognition of cases of apparently continuous self-fertilisation, the abandonment was made in 1868 by Darwin himself, as I have already shown. But Willis' abandonment seems to me part of an implied contention that Charles Darwin's generalisations are no longer a sufficient basis for floral biology. He seems to think that if the Knight-Darwin Law is not true, the fundamental principles underlying the study of the mechanism of flowers must be sought elsewhere than in Charles Darwin's works. In this point of view I think he is mistaken.

The attitude of the earlier writers towards the problem of cross-fertilisation seems, if I may venture to say so, to be elsewhere rather badly treated by Willis (*loc. cit.*, p. 45). Take the following passage: "The advantages of cross-fertilisation are often great, and frequently enormous, and as at the first glance they appear to be obtained at little or no cost, we are inclined to expect this method of propagation to prove almost universal. The earlier workers at this subject in fact set out with the idea that cross-fertilisation was, so to speak, the primary object of a flower's existence, whilst self-fertilisation was actually harmful." Almost the whole of this seems to me to be unintentionally misleading.

That all "earlier workers" did not consider cross-fertilisation the primary object of a flower's existence, is shown by the following passage from "Cross- and Self-Fertilisation," p. 3: "We should always keep in mind the obvious fact that the production of seed is the chief end of act of fertilisation, and that this end can be gained by hermaphrodite plants with incomparably greater certainty by self-fertilisation than by the union of the sexual elements belonging to two distinct flowers. Again, reviewing in 1862 ('Cross- and Self-Fertilisation,' p. 8) his own treatment of the question in the "Fertilisation of Orchids" (1862), Darwin says: "I should have added the self-

evident proposition that the propagation of the species, whether by self-fertilisation or by cross-fertilisation . . . is of paramount importance." Willis, therefore, seems to me completely wrong if he includes Charles Darwin among the earlier who considered cross-fertilisation the primary object of a flower's existence.

Nor, I think, is self-fertilisation ever treated by Darwin as positively harmful, though *perpetual* self-fertilisation is so treated. Self-fertilisation is constantly and correctly considered as less advantageous than cross-fertilisation—and in this sense (always bearing in mind the paramount importance of fertilisation of some sort) it may be said that self-fertilisation is relatively harmful.

Whatever may be the case with other naturalists, Darwin was certainly not inclined to expect cross-fertilisation to prove almost universal. Speaking of orchids, he says ("Fertilisation of Orchids," ed. 1, p. 359): "Considering that the anther always stands close behind or above the stigma, self-fertilisation would have been an incomparably safer process than the transport of the pollen from flower to flower. It is an astonishing fact that self-fertilisation should not have been an habitual occurrence." He saw clearly that plants pay a price for being so constructed that cross-fertilisation is possible, in fact, he saw that the evolution of the flower is the result of a gain and was accounted between the advantage of cross-fertilisation and the risks and injuries consequent on the flower being open instead of closed, and therefore chasmogamic instead of cleistogamic. And this is in all essentials the theory which Willis ("Flowering Plants and Ferns," p. 46) gives as Macleod's, and proposes as a basis for floral biology, when the Knight-Darwin Law has been abandoned, and H. Müller's theory also given up. I am not able to read Macleod in the original Dutch, but it would appear from Willis's paper in *Science Progress*, 1896, that Macleod's contribution to the subject is full of valuable matter, but the essence of his theory (as given by Willis) seems to me to contain nothing with which my father was not familiar. What I object to is the tendency to condense Charles Darwin's contribution towards floral biology to a Knight-Darwin Law, and then, when the abbreviated statement does not explain everything, to abandon—not so much the law—but the general point of view which can only be gathered from Darwin's books as a whole.

The fact that some modern biologist uses the Knight-Darwin Law in an inverted way, *i.e.* in a manner the reverse of Charles Darwin's way of using it. It was not to him a basis for the investigation of floral structures, but a generalisation extracted from that subject to serve as a foundation for the study of wider questions, such as the origin of sexuality. This is clearly shown in a passage from the first edition of the "Fertilisation of Orchids," where, after enunciating nature's abhorrence of perpetual self-fertilisation, Darwin goes on ("Fertilisation of Orchids," 1862, p. 359): "This conclusion seems to be of high importance, and perhaps justifies the lengthy details given in this volume. For may we not further infer as probable that some unknown great good is derived from the union of individuals which have been kept distinct for many generations?" H. Müller, perhaps, understood my father's use of the Law when he said ("Fertilisation of Flowers," p. 22) that the Knight-Darwin Law is not necessary for the elucidation "of the forms of flowers." But he would hardly have said as much of Knight's statement, that hermaphrodite flowers are adapted for intercrossing—which is the very foundation of the science of floral mechanism.

I now pass on to another writer—Knuth—who, in his useful "Blutenbiologie," seems also to be open to criticism in his treatment of the Knight-Darwin Law. In speaking of H. Müller's great work, he says ("Blutenbiologie," vol. I, p. 25): "The laws of Knight, Darwin, Hildebrand, Delpino gave no explanation of the numerous cases of efficacious self-fertilisation, nor of cleistogamy." Here Knuth does not seem to remember the conditions of thought under which the Knight-Darwin Law came into existence. As Loew ("Einführung in die Blutenbiologie," p. 143) has well said, self-fertilisation was formerly assumed to be the rule in hermaphrodite plants. In calling attention to the existence and importance of cross-fertilisation in hermaphrodites, Knight and Darwin assumed the existence of self-fertilisation. From the point of view of floral biology the important thing was the recognition of cross-fertilisation, and the law in which, unfortunately, this conclusion has been taught, need not explain the fact which the framers of the law assumed to be a part of common knowledge. With regard

to cleistogamy, in its ordinary sense it is clear that there is no contradiction between the Knight-Darwin Law and the facts, as Loew has clearly pointed out ("Einführung," p. 144).

After the passage quoted above, Knuth goes on: "In the place of the one sided law of the above-named naturalists (of which the general truth remains unproven) Müller set up a law, proved directly by Darwin's experiments and indirectly by the reproductive arrangements of plants in general, but especially by those of flowering plants. The law, namely, that 'when the offspring of cross-fertilisation come into serious conflict in the struggle for life with the offspring of self-fertilisation, the former (cross-bred) win the day.' Only when this contest is absent can self-fertilisation suffice for reproductions for many generations."

I confess that this law is to me unsatisfactory. We ask ourselves "when is the struggle between cross- and self-bred offspring absent?" Clearly when all the offspring are of one kind, *s.e.* all cross-bred or all self-bred in a dioecious plant where all offspring are cross bred, there is no question of self-fertilisation. In a plant with purely cleistogamic flowers, all offspring would be necessarily self-bred, and the law would imply that cleistogamic perpetuation may suffice. The law, therefore, amounts to this that self-fertilisation will suffice only when it is unavoidable. This is as much as to say that any form of fertilisation is better than none. It is best to neglect this form of Müller's hypothesis, and to seek his meaning in his simpler and broader statements. In summing up his discussion in the "Historical Introduction," he says ("Fertilisation of Flowers," p. 23) "There is a good foundation, therefore, for the demand that the explanation of floral mechanisms shall rest only on the sufficient and demonstrable assumption that cross-fertilisation yields more vigorous offspring than self-fertilisation."

We have therefore as the chief points in Müller's theory

- (1) Fertilisation at any price.
- (2) The increased vigour of cross bred offspring.

Let us consider these more fully, and first for the conclusion that self-fertilisation is better than no fertilisation. This is a proposition which Müller has insisted on in the most interesting and instructive way, but it surely is not very novel in principle. In a passage already quoted, Darwin renewing, in 1876, his story of 1862 ("Cross- and Self Fertilisation," p. 8), says: "I should have added the self-evident proposition that the propagation of the species, whether by self-fertilisation or by cross-fertilisation . . . is of paramount importance. Hermann Müller has done excellent service by insisting repeatedly on this latter point." No one had a higher respect than my father for Müller's work, and he had no disrespectful intention in describing Müller's contribution to the theory as self-evident. The interesting point is that these views did not strike him as original, because they had already occurred to himself.

That Müller based the explanation of floral mechanism on the experimental results of cross fertilisation cannot be considered as a new departure. I should have imagined it to be notorious that this was Charles Darwin's view, if it were not that we find Knuth and others describing Müller's theory (in which this is the essential thing) as a great law of nature.

In a letter ("Life and Letters," ii, p. 291) to the late Asa Gray (September 10, probably 1866), Charles Darwin wrote: "I have seen the young seedlings from the crossed seed exactly twice as tall as the seedlings from the self fertilised seed . . . If I can establish this fact . . . in some fifty cases . . . I think it will be very important, for then we shall positively know why the structure of every flower permits, or favours, or necessitates an occasional cross with a distinct individual."

It seems to me that Charles Darwin's generalisations in regard to flowers may be summed up thus:—

- (1) First comes what he called the self-evident proposition that fertilisation of some sort is of paramount importance. This is of the nature of an axiom.
- (2) Then comes the direct observation that the vast majority of flowers are open. From this fact alone we should be justified in concluding that there is some advantage in cross- as compared to self-fertilisation, which advantage makes it worth while for flowers to run the risks and incur the expenditure necessarily connected with openness, and avoidable by cleistogamy. The

¹ I use the words *cross-bred* and *self-bred* to denote the offspring of cross- and self-fertilisation; we thus avoid the slightly obscure phrases *cross-fertilised* and *self-fertilised* seedlings which occur in Darwin's books.

² I am far from wishing to suggest that H. Müller's work does not contain much that is new and valuable; I am here considering only its fundamental basis.

innumerable adaptations for pollen-transport suggest and strengthen the same conclusion. But this is, properly speaking, only an elaboration of the fact that flowers are open.

(3) Direct experiment demonstrates the nature of this surmised advantage of cross-fertilisation over self-fertilisation.

As already pointed out, the Knight-Darwin Law in its usual form, *s.e.* no plant is self-fertilised *ad infinitum*, or in its improved form—"Nature abhors perpetual self-fertilisation"—is a generalisation drawn from observations on structure and experiments on crossing, the value of which in Darwin's opinion was rather its applicability to the problem of sex in a wide sense, than its use as a basis for understanding the mechanism of flowers.

The point which seems to me important in the history of the subject, is that the above generalisations, which are in substance to be found in Darwin's works, are still the foundation-stones of floral biology, and would stand as firmly if the Knight-Darwin Law had never been formulated. For the naturalist who takes a wider field, and studies the origin of sex and the action of changed conditions, the existence or non-existence of perpetual self-fertilisation must always be an important question; but the law in which its non-existence is formulated, is not a fundamental canon of floral biology. FRANCIS DARWIN

BOTANY AT THE BRITISH ASSOCIATION.

THE subject of alternation of generations in plants played a prominent part in the work of the Botanical Section. The President (Prof. Bower) devoted a considerable portion of his address to the controversial questions connected with "the great enigma of the alternation of generations" in green plants Mr. Lang, of Glasgow University, and Prof. Klebs, of Halle, contributed important papers on this subject, and these were followed by a general discussion on the problems of alternation. Mr. Lang gave an excellent summary and critical review of our present knowledge concerning alternations of generations in the Archegoniate. The recent work of this investigator on some striking cases of deviation from the normal life-history of ferns, must be ranked among the most important contributions germane to this subject which have appeared in recent years. In concluding his account of some of the main factors in alternation, the author suggested three subsidiary questions as worthy of attention—the probable line of descent in archegoniate plants, the bearing of the cytological data on the question, and the significance to be attached to apogamy and apogamy.

Prof. Klebs' paper dealt with the alternation of generations in the Thallophyta, a subject which he was particularly well fitted to discuss from a critical standpoint. After taking a general survey of the various divisions of the Thallophyta, Prof. Klebs referred more especially to certain cases which have a more direct bearing on the question of the first appearance of a regular alternation of generations. The majority of the Algae and Fungi have two or more kinds of propagation, each of which necessarily depends upon definite external conditions. According to the conditions the different kinds of propagation may appear on the same or on different individuals, independently or in any succession. The fertilised ovum in sexual forms does not differ essentially on germination from another propagative cell. In none of these cases is there any reason for speaking of an alternation of generations. In conclusion, the author briefly referred to the possible connecting links between the Algae and Archegoniate. Sir Edward Fry, Dr. Scott, Profs. Marshall Ward and Marcus Hartog took part in the discussion which followed the two contributions by Mr. Lang and Prof. Klebs.

Another important item in the programme of Section K was a semi-popular lecture by Dr. F. F. Blackman, on the breeding mechanism of plants. The lecturer gave a clear and interesting summary of the progress of experimental work on the phenomena of gaseous exchange between a green plant and the medium in which it grows, concluding with an account of some recent investigations which have not yet been published.

Algae and Fungi.—The Committee on Fertilisation in the Phaeophyceae reported very satisfactory progress in the researches on the Fucaeae and Dictyotaceae. Mr. Lloyd Williams, of Bangor, whose researches have been carried out under the auspices of the Committee, gave an account of his important work on the reproduction of *Dictyota dichotoma*. *Dictyota*, an annual brown seaweed, germinates during the

summer and begins to form its reproductive cells in July. The tetraspores are produced throughout the season, but the sexual cells show a remarkable periodicity. The author described the fertilisation of the oospheres by the motile antherozoids, and expressed the opinion that there are strong reasons for concluding that the factors which determine the maturation and liberation of the sexual cells, and the fertilisation of the oospheres, is the amount of illumination to which the plants are exposed.

Prof Phillips, of Bangor, contributed a paper on the form of the protoplasmic body in certain Florideae. In *Ceramium rubrum* and other species a strong strand of protoplasm runs along the axial cells from pit to pit. In *Dasya coactoma*, the branches of limited growth run out into pointed uncoated filaments, the cells of which are large. Across the vacuole of these cells running from pit to pit occurs a thread of protoplasm much more delicate than the corresponding structure in *Ceramium*. In *Callithamnion bryoides*, threads of protoplasm, which exhibit incessant movement, radiate from a cushion lying over the pit and end blindly on the vacuole. All these phenomena point to the great physiological importance of the pit-communication between cell and cell.

Prof Errera, of Brussels, communicated the results of some recent work on the structure of the yeast cell; his investigations led him to the following conclusions: (1) a relatively large nuclear body exists in each adult cell; (2) young cells contain no such body, at a later stage the old nuclear body divides, one of its two daughters wanders through the narrow connecting channel into the young cell; (3) after the division is complete, the two cells are kept together by a mucilaginous neck shaped pedicel; (4) carbohydrates are stored up in yeast in the form of glycogen, which accumulates or disappears from the vacuoles very rapidly, according to conditions of nutrition and growth.

Mr. Harold Wager also presented a communication on the same subject; he referred to the existence of a deeply stainable body, regarded by most observers as a nucleus, and of a vacuole in close contact with the nucleus. During the division of a cell a portion of the nucleus and of the vacuole passes into the daughter-cell. Mr. Wager pointed out certain errors in the work of Hieronymus; and expressed the opinion that the "nucleus" of the yeast possibly represents an early stage in the development of the vegetable nucleus; it might be designated a proto-nucleus. Mr. Wager also gave an account of his researches on the rare fungus *Polyphagus euglenae*, a parasite on *Euglena viridis*. The material was obtained from a filter-bed at Keighley. Mr. Wager was able to follow in detail the methods of spore and zygospore formation; he noted the interesting fact that the male cell is larger, and possesses a larger nucleus than the female cell.

Prof. Marshall Ward gave an account of a new potato disease which appears to be fairly common, but has hitherto usually been confounded with the disease caused by *Phytophthora*. The pathology of the disease was dealt with, and the author referred to certain external symptoms which enable a practised eye to distinguish diseased plants from those suffering from the attacks of *Phytophthora*. An interesting feature of the disease is that the fungal hyphae appear to prepare the way for the entrance of bacteria and other organisms into the tissues of the host-plant. The same author contributed a second paper, in which he described the action of *Phusicium* as a wood-destroying fungus.

Mr. Trow, of Cardiff, gave an account of the cytology and reproduction of *Archips americana* var. *cambridge*. He described the nuclear division in the oogonium and antheridium; also the occurrence of fertilisation as in *Saprolegnia mixta* and *S. dichna*.

Mr. Ellis, of Cambridge, contributed a note on a method of obtaining material for illustrating smut in barley.

Pteridophytes and Gymnosperms (Recent and Fossil).—Mr. Lang announced the discovery of the prothallus of *Lycopodium flavescens*. A few prothalli were found wholly imbedded in the peaty soil underlying a patch of moss; three of them bore young plants, and a number of slightly older plants, the prothalli of which had disappeared, were found in the same spot. The prothalli, which present a general resemblance to those of *Lycopodium annotinum*, are of considerable size, completely devoid of chlorophyll, and fairly well provided with rhizoids. Their form is that of a thick fleshy cake, which soon becomes thrown into folds by the unequal growth of the margin. The

sexual organs are borne on the upper surface, both antheridia and archegonia may be present at the same time.

Dr. Scott gave a short account of some of his recent work on the anatomy of Coal-measure plants; the most important of his contributions was a description of the structure of a new form of the genus *Medullosa* from the Lower Coal measures of Lancashire. This extinct type of Palaeozoic plants has not hitherto been recorded from a British locality, and has not previously been found in rocks of Lower Coal-measure age. The material on which the description was founded was obtained by Mr. Lomax, and the excellent sections, of which micro-photographs were shown on the screen, were prepared by this able worker. Dr. Scott showed that the type of structure represented by the Lancashire *Medullosa* is that of a polytelic *Heterantrum* which bore *Myeloxylon* petioles. The same author exhibited photographs of an unusually fine specimen of the Halonial branch of a *Lepidodendron*, allied to *L. fuliginosum*, recently discovered by Mr. Lomax. Other contributions by Dr. Scott dealt with an English example of the interesting Palaeozoic fern *Boryopteris*, and with a remarkably fine example of *Zygopteris* from the Williamson Collections of Coal measure plants in the British Museum.

Mr. A. C. Seward described the external features, internal structure and geological history of the Malayan fern *Matonia*. The anatomical investigation was founded on some material received through the kindness of Mr. Shelford, of the Sarawak Museum. The stem of *Matonia pectinata* is characterised by an arrangement of vascular tissue which appears to be unique among recent ferns, there are two annular sets, and occasionally also an axial strand of xylem and phloem traversing the creeping rhizome. The genus *Matonia* has usually been regarded as a type apart, and the anatomical characters emphasise the isolated position of the genus. The two living species of *Matonia* are no doubt the survivors of a tribe of ferns widely distributed during the Rhetic and Jurassic periods.

Mr. C. E. Jones, of Liverpool, contributed a paper on the anatomy of the stem of certain species of *Lycopodium*, his communication was of the nature of a preliminary note on the subject of the general anatomical investigation of *Lycopodium*, on which he is at present engaged.

Mr. Pearson, of Cambridge, described the apogontropic roots of the Australian Cycad *Savania spectabilis*; he drew attention to the occurrence of colonies of *Anabaena* in the intercellular spaces of the cortex.

Physiology and Natural History.—Prof. Errera discussed the theoretical calculation of an osmotic optimum. Recent researches made by Dr. F. Van Rysselberghe, of Brussels, have shown that vegetable cells generally answer an osmotic stimulus by an appropriate osmotic reaction, and that the relation between stimulus and reaction follows, within wide limits, the "law of Weber." Hence results the possibility of predicting the existence and value of an osmotic optimum. The same author also contributed a note on the unit to be adopted for osmotic measurements.

Mr. Francis Darwin read a paper of special interest on the Knight Darwin Law. (This paper is printed in full in another part of the present number.)

Prof. Reynolds Green gave an account of some results which he had obtained confirmatory of Buchner's work on the enzyme of the yeast plant. Prof. Green found that if the yeast experimented on is in a state of active fermentation, the alcohol-producing enzyme can be procured as Buchner has stated. He described the method of investigation adopted, and concluded by stating that the enzyme obtained from yeast agrees in an important respect with other enzymes.

Prof. C. de Candolle, of Geneva, gave the results of a comprehensive comparative study of petiole leaves, with special reference to the number of species possessing such organs, their distribution among the various natural orders, and their mode of growth.

Mr. Burkill, of Kew, dealt with changes in the sex of willows. In the genus *Salix* flowers of both sexes are occasionally present in the same catkin, and the sexual organs are sometimes found to be intermediate in structure between stamens and carpels. Mr. Burkill gave the results of his examination of an extensive series of specimens and published records.

Mr. S. T. Dunn contributed some notes on the origin of railway-bank vegetation.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

SPEAKING as chairman of a meeting of the Associated Societies of Edinburgh University on Tuesday, Mr Balfour expressed his views on examinations as follows:—I think the time is not very far back when the idea was prevalent that after all a University was little more than an examination machine for stamping a certain number of students with a hall-mark, indicating that they had satisfied a certain number of examinations, and that they possessed a certain amount of knowledge on a certain amount of subjects. But that idea belongs to the past, and everybody who realises how the University machinery may do the work of higher education in the country has long recognised that the University to be at its best must not be an examining University merely or particularly, but what is wanted is a teaching University. I do not wish to overstate the case against examinations. I have always insisted that they are a necessity. They are evil, necessary evils, evils which no skill on the part of the examiner, no dexterity on the part of those responsible for University organisation, could wholly remove. That an examination may be a good test of intellectual capacity I cannot deny when I remember the numbers of eminent men who in after life have been in the very first rank of scientific and philosophical investigators, or in the very front rank as men of letters, and who were all so distinguished in examination. But while they were reading for examination they were occupied in considering not what was the sort of truth, not what was the best method of advancing the special study in which they were engaged, and so increasing the science of the world. Not at all. They were occupied to a large amount with an immense variety of subjects, different altogether and at the same time ready for immediate use—the last thing a practical man ever does. The serious man puts out of his head that which is not necessary and is, indeed, superfluous. He focuses his mind upon the work immediately before him, and, though no doubt he may see to the right or to the left more collateral subjects which have a bearing upon the main question, he certainly is never in the position of the unhappy victim of examination, who is going over in his head, before entering the room, all the various problems it is necessary to have at his finger ends if he is to satisfy the gentleman who is examining him.

SIR W. H. WHITE delivered an address on engineering education at the Institution of Junior Engineers on Friday last. In the course of his remarks he said he was constantly asked what course of training he would recommend for youths intended to become engineers. His advice had always been the same, and it was based on personal experience and extensive observation. Practical training in the workshop, factory, ship-yard, or other engineering establishment was, he considered, best begun when a lad was fresh from school. "Roughing it" then came easy, observation was quick, while the facility for acquiring handicrafts and manual dexterity was greatest. Familiarity with the habits and modes of thought of workmen was readily gained also, and was a valuable acquisition. During this period of practical training it was most desirable that scholastic knowledge should be maintained or extended. If this programme were carried out, a young man finished his practical course without loss of education; and if he had the means and the capacity, he was well prepared for entry into a technical college at an age which permitted him to obtain the full benefit of theoretical training and laboratory work. With ability and energy commensurate to the task, a student thus prepared, and bringing with him considerable practical experience, ought to reap the greatest advantage from the higher course of study, and to be ready for actual work when it was completed. His observation and experience as student and professor convinced him that many youths entered technical colleges who, from want of preliminary education or of ability, could never hope to benefit much, if at all. It would be a kindness in such cases if entry were guarded by such preliminary tests and inquiries as would prevent waste of time, and permit other and more suitable training to be undergone. Perhaps the ideal system of training was that which permitted an engineering pupil to continue his scholastic training side by side with the preliminary practical experience, as the medical student attached to a hospital did. Selected men, having proved their capacity, could then proceed to a course of higher technical training without losing all contact with practical work. The latter condition could be met by arranging suitable intervals when

students would suspend their studies of theory and go out to the scenes of engineering operations, where they could compare the lessons learnt in the study and laboratory with actual procedure in carrying on work.

We are glad to see that an attempt is being made to co-ordinate the educational institutions in Bristol, and so prevent the present overlapping of work and conflict of interests. At a recent meeting of the Technical Instruction Committee of the County Borough Council the following resolution was adopted:—"That the governors of the Bristol University College, the governors of the Merchant Venturers' Technical College, and the Bristol School Board, be requested to send three representatives each to meet a sub-committee of the Technical Instruction Committee, for the purpose of taking into consideration the needs and resources of the city as a whole, with a view of combining all parties in one comprehensive plan for the supplying of such technical instruction as the circumstances of Bristol require."

SCIENCE reports the following gifts to educational institutions in the United States.—The will of the late Colonel Joseph M. Bennett, who during his life time had made generous gifts to the University of Pennsylvania, leaves to the University property valued at 400,000 dollars. The money is to be used for the higher education of women.—A sum of money, said to be 150,000 dollars, has been given by friends of Barnard College to pay the entire indebtedness of the College due to its removal to the new site adjacent to Columbia University.—A donor, whose name is withheld, has given Wellesley College an astronomical observatory and a telescope, said to be of large size.—Vassar College receives 10,000 dollars by the will of the late Adolf Sutro, of San Francisco. The same College has been given 1000 dollars by Senator Coleman, of Michigan, the income to be used to purchase books and instruments for the astronomical observatory.—The annual report of President Low to the Trustees of Columbia College states that during the year the University received 346,409 dollars for permanent endowment and 43,909 dollars for current uses.

THE *Athenæum* states that the Joint Committee of the bodies concerned in secondary education, which includes representatives of the universities and the administrative authorities, has been summoned to meet on November 5, when the Government Education Bills will be taken into consideration. It seems probable, from what has taken place during the recess, that the constituent bodies will not deem it advisable to urge the Government to immediate legislation on the subject of local authorities.

SCIENTIFIC SERIALS.

American Journal of Science, October.—The compressibility of colloids, with applications to the jelly theory of the ether, by C. Barus. Various colloids were compressed in capillary tubes with mercury terminals. A solution of gelatine or albumen in water was found to have a low compressibility, and a solution of india-rubber in ether was taken as a type of a highly compressible colloid. When the colloid was compressed by the mercury, the meniscus would occasionally give way, and a droplet of mercury be projected through the substance of the colloid to a distance of 12 cm. or more. This has an interesting application to the problem of the motion of material bodies through a solid ether. The mechanism of this motion is not yet explained, but there is probably a temporary liquefaction of the colloid in front, and a subsequent solidification behind the moving body.—Eolian origin of loess, by C. R. Keyes. The amount of dust brought up out of the Mississippi valley into St. Louis is about one-hundredth inch in a day when the wind blows. An open book placed in a protected nook was after a few hours of wind so covered with dust that the print could not be distinguished. Probably the rate of deposition of the Mississippi loess is one-tenth of an inch per annum. Being spongy and absorbent, the loess retains moisture in the dry season, and gives rise to a luxuriant vegetation.—Detection of sulphides, sulphates, sulphites, and thiosulphates in the presence of each other, by P. E. Browning and E. Howe. To about 0.1 gr. of the substance dissolved in 10 cc. of water, add an alkali to slightly alkaline reaction. Add zinc acetate in distinct excess, and filter. The precipitate may be tested for $\text{S}_2\text{O}_3^{2-}$ or acidifying, in the usual manner. To the filtrate add acetic acid

in slight excess, and barium chloride, and filter through a double filter. To the filtrate add iodine until the solution takes on a permanent yellow tinge, and then bleach with stannous chloride. A precipitate indicates the sulphate. Filter, add bromide water in slight excess to the filtrate, bleaching again with stannous chloride. A precipitate on adding bromine indicates a thiosulphate originally present.—The origin and significance of spines, by C. E. Bescher (concluded). Spineous forms were simple and inornate during their young stages, and were all derived from non-spineous ancestors. Spines represent an extreme of superficial differentiation which may become fixed in ontogeny. Spinosity represents a limit to morphological and physiological variation. After attaining the limit of spine differentiation, spineous organisms have no descendants, and out of spinosities no new types are developed.

THE following are the titles of the more important papers in systematic and geographical botany contained in the *Journal of Botany* for August-October.—Two new genera of Compositae, *Pseudotrachia* and *Adenogonum*, from Africa, by W. P. Hiern; the Mosses of Cheshire, by J. A. Wheldon; a new genus of Ericaceae from Angola, *Evilathus*, by W. P. Hiern; critical notes on some species of *Ceratium*, by F. N. Williams; new species of *Crasulla*, by S. Schonland and E. G. Baker, the Flowering Plants of Novaya Zemlya, by Colonel H. W. Feilden.—Mr. W. Whitwell establishes the occurrence of *Botrychium matricariaefolium*, and of its subspecies (or distinct species) *lanceolatum*, as British plants. In their Notes on Freshwater Algae, Messrs W. and G. S. West propose the establishment of a new genus *Stiprococcus*, near to *Peronella*.

SOCIETIES AND ACADEMIES.

MANCHESTER

Literary and Philosophical Society, October 4.—[Commo Melville, President, in the chair.—The President referred to the loss sustained by the Society through the deaths of Mr. H. M. Ormerod, Dr. R. M. Pankhurst, Dr. James Rhodes, and Mr. John Wright, ordinary members, and of Prof. Ferdinand Cohn, Lord Playfair, and Mr. Osbert Salvin, F.R.S., honorary members.—Mr. H. W. Freston exhibited a male specimen of *Asperula phalaritis*, an extremely rare species of spider which by itself represents the genus *Asperula*, whose nearest congener is the genus *Stenodora*. The present individual is the only male that has been found, at all events in recent years. The habitat of this species has hitherto been unknown, but it would seem now that it is a simple Theridion snare in grass amongst rocks. The most striking features of the genus are a denticulated edge to the cephalothorax, and a denticulated socket in the front of the abdomen, forming a stridulating apparatus which would produce a squeaking noise when rubbed against the rough under edge of the thorax.—Mr. John Butterworth read a paper on the structure of some fragmentary specimens of a new *Paranotus*, which he concluded to be the roots of *Heterangium thidodes*. The special feature of these roots was the presence of a distinct secondary thickening, which is unknown in the other species of *Paranotus*.—In a second paper, Mr. Butterworth dealt with the presence of a leaf-sheath surrounding the nodes of some of the Calamites of the Lancashire Coal-measures. Such a sheath has not been described before from British Calamites.

PARIS.

Academy of Sciences, October 17.—M. van Tieghem in the chair.—On an old alloy, by M. Berthelot. The alloy contains copper, lead, and small quantities of tin and zinc. The oxidation has taken place in such a manner, that removal of the external coating of rust shows an apparently reddish metal underneath, probably cuprous oxide. From its external appearance the metal might have been taken for pure copper.—Physiological researches on the contraction of the *sphincter ani*, by MM. S. Arloing and Edouard Chantre. Experimental results confirming the conclusions arrived at in a previous paper with regard to the existence of a number of sensitive fibres in the two symmetrical nerves of the sphincter.—On the resultant of two equations, by M. P. Gordan.—On differential equations of the second order with fixed critical points, by M. Painlevé.—On the variation of dielectric constants with temperature, by MM. H. Pellat and P. Sacerdoti. Measurements were carried out with paraffin and ebonite at temperatures varying between 11° and 33°. The dielectric constant of paraffin diminishes with rise of temperature, that of ebonite, on the other hand,

increasing on warming.—On the duration of emission of Röntgen rays, by M. Henri Morize. The rays from a Crookes' tube were allowed to fall through a narrow slit upon a photographic plate, the latter being rapidly rotated at a constant known velocity. The effect of rotation would be to widen the photographic image of the slit if the time of emission were appreciable. The results obtained were in general agreement with those of M. Colardeau, several images of the slit being formed, separated by equal intervals for each discharge in the primary in the coil, corresponding to successive discharges in the tube. The average duration of total emission was about one thousandth of a second. On a new action undergone by light in traversing certain metallic vapours in a magnetic field, by MM. D. Macaluso and O. M. Corbino. A ray of polarised sunlight is passed through a sodium flame placed in an intense magnetic field, then successively through a second nickel and a cylindrical lens, is then received on a concave Rowland grating, and the second diffraction spectrum observed through a micrometer eye piece. Under these conditions, on completing the circuit round the electromagnet parallel, bands appear on each side of the two D lines, which are displaced on rotating the analyser, the axis of each ray following the direction of the current. A lithium flame exhibits similar phenomena, but not so well marked as with sodium.—On a new hydrated chromium oxide, by H. G. Baugé. The new hydrate, which has the composition $\text{Cr}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, is obtained by the action of boiling water upon the carbonate in the absence of air.—Action of sodammonium upon arsenic, by M. C. Hugot. The single product of the reaction is AsNa_2 .—Researches on double iodides and borates, by M. H. Allaire. A mixture of a borate and a metal is heated in iodine vapour. The double salts obtained in this way were of the type $\text{6RO} \cdot \text{BBO}_3 \cdot \text{RI}_2$, where R=Mg, Zn, Cd, Mn, Ni, Co, or Fe.—On the solubility of camphor, by MM. C. Istrati and A. Zaharia. Camphor is appreciably soluble in water, the camphor in solution affecting the density, and having a perceptible rotation. The solubility is much greater in aqueous hydrochloric acid, a chlorhydrin perhaps being formed. The solubility in the latter case appears to diminish with rise of temperature.—Researches on incandescent lamps charged with an explosive mixture of methane and air, by MM. H. Couriot and J. Meunier. The glowing filament of an incandescent lamp was allowed to come in contact with an explosive mixture of marsh gas with air, under varying conditions. In no case did an explosion take place.—On the transformation of fat by direct oxidation, by M. Hannot. Fat, treated with ozonised oxygen, gained considerably in weight; in one case as much as 23 per cent. No reducing substance appeared to be formed, tests for sugar, starch, cellulose, formic and oxalic acids giving uniformly negative results. The products of the oxidation appear to be chiefly fatty acids.—On the cause of the spiral structure of the roots of certain Chenopodiaceae, by M. Georges Fron. The asymmetrical structure, which gives the fibrovascular bundles in a transverse section the appearance of a double spiral, is caused by the mechanical compression of the cotyledons in the radicle.—On *Blepharopoda lauriana*, by M. E. L. Bouvier.—Anatomy and physiological functions of the arthropodous organs or aquatic lungs of some Holothuria, by M. L. Borda. These organs appear to have numerous functions, as they are concerned in breathing, moving, in excretion, and in the production of numerous amebocytes.—The pegmatic and granitic lobes of the rock masses in contact with the granite of Arège, by M. A. Lacroix.—On the circulation of water in the Rhône glacier, by M. E. A. Forel. Fluorescence was introduced at various points, and the times which elapsed before its appearance in the main torrent noted. The velocities found were of the same order as those for the free stream, whence the conclusion is drawn that in the interior of the glacier the water circulates without stopping in basins, reservoirs, or lakes, and hence there is no sub-glacial lake under the Rhône glacier.—Results obtained in an experimental balloon ascent on August 23, by MM. G. Hermite and G. Besançon. The curves obtained from the self-registering baro-thermograph were unusually good, the greatest height registered being 7300 metres, with a corresponding minimum temperature of -50°C .

NEW SOUTH WALES.

Linnean Society, August 31.—Mr. E. G. W. Palmer in the chair.—Contributions to a knowledge of the fauna of British New Guinea. No. 1. Communicated by T. Steel. This com-

FOURTH INTERNATIONAL CONGRESS OF ZOOLOGY.

CAMBRIDGE MEETING, 1898.

List of Subscriptions and Donations Paid (in London) to the Treasurers up to April 28th, 1898

LOSSES PAID OVER £20,000,000.

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.

The Photo Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduc-
tion of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs.

The Instrument is fitted with
an Aluminium Body, 6 in.
Azimuthal Circle, reading with
vernier to one minute of arc,
4 in. Compass, divided to half
degrees. Telescope with erect
and inverting Lycopodium, rapid
rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description
of the Instrument sent free on application

SOCIETY FOR PROMOTING CHRISTIAN KNOWLEDGE.

TWO HUNDRED YEARS the History of the S. P. K., 1683-1883. This Volume gives a fairly full account of the circumstances in which the Society originated, and of the various works carried on by it throughout the two centuries. The information contained in the Volume is drawn from the main from the Society's Minute Books, and the several other records of the Society, and is more complete account of church life, and work during the last two centuries than could be had from any other source. By the Rev. W. OSBORN ALLEN, M.A., and the Rev. F. J. MURPHY, M.A., Secretaries of the Society. Demy 8vo. With a Frontispiece, and several Illustrations. Buckram boards, 10s. 6d.

HISTORICAL CHURCH ATLAS Illustrating the History of Eastern and Western Christianity until the Reformation, and that of the Anglican Communion until the present day. By EDMUND McCURR, M.A. Containing 16 Coloured Maps, besides some 50 Sketch Maps in the Text. Demy 4to, cloth boards, leather back, 10s.

"Every student of the Church history in the past or of her world wide work in the present should make haste to add this handsome volume to his books." *Review*

"Both the readers of ancient Church history and of modern missionary records will find abundant materials in it for their own use." *Cont. Rev.*

"A great deal of labour and sound scholarship has gone to the making of this atlas." — *Leading*

THE ANCIENT HEBREW TRADITION AS ILLUSTRATED BY THE MONUMENTS. A Protest against the Modern School of Old Testament Criticism. By Dr. ERIC HORNELL, Professor of Semitic Languages in the University of Munich. Translated from the German by EDWARD McCURR, M.A., and EDWARD CROSSLIE. With Map. Large Post 8vo, buckram boards, 12s.

"Under the weight of Dr. Hornell's cumulative evidence the first fortress of the 'Higher Criticism' will have to be promptly evacuated or surrendered at discretion. The book has been admirably translated by Mr. McCur and his co-editor." — *Daily Chronicle*

"As a protest against the modern school of Old Testament criticism as actually committed the work was one of the most valuable yet published." — *Pall Mall Gazette*

LONDON: NORTHUMBERLAND AVENUE, CHARING CROSS, W.C. 43 QUEEN VICTORIA STREET, E.C. 4, BRIGHTON: 129 NORTH STREET

THE CERES SYSTEM.

There is no arrangement so simple for keeping correspondence, &c. Papers can be arranged in a moment either alphabetically or according to subjects, and there is no mechanism to bother one or get out of order.

The Cheapest File in the Market. Six times the capacity of any binding File, and one place to refer to instead of six.

In Wood, covered cloth. Size 17" x 12" x 10" high. Capacity, 1,800 Papers. Price, with set of Alphabetical Guides and 2 Blanks, 12s. 6d. Extra Blanks for writing own headings, 2s. per doz. For other varieties and sizes of Box Files, Cabinets, Writing Tables, Standing Desks, &c., see Explanatory Pamphlet, Post free.

EPPS' COCOAINE.

COCOA-NIB EXTRACT

The choicest roasted nibs (broken up beans) of the natural Cocoa on being subjected to powerful hydraulic pressure, give forth their excess of oil, leaving for use a finely flavoured powder—"Cocaine," a product which, when prepared with boiling water, has the consistence of tea, of which it is now, with many, beneficially taking the place.

Its active principle being a gentle nerve stimulant, supplies the needed energy without unduly exciting the system. Sold only in labelled tins. If unable to obtain it of your tradesman, a Tin will be sent post free for 9 stamps.—JAMES EPPS and Co., Ltd., 11, Moorgate Street, London.

[All Rights are Reserved]

"APPS-NEWTON" 18-inch INDUCTION COIL.

Many of the leading X-Ray workers are now using the 18" APPS-NEWTON COIL in preference to the smaller sizes, owing to its greater penetrating power in thick parts of the body, and shortness of exposure, and we are now making them for some of the principal Hospitals. A photograph through the body of an adult showing heart, ribs, collar-bone, shoulder-blades, &c., most clearly taken by Mr Webster in 3 minutes with our 18" Coil, can be seen at
3 FLEET STREET

Dr. J. MACINTYRE, of Glasgow, says:—My latest experimental work in *instantaneous* X-Ray photography and cinematographic records to show movements of the body by means of the Roentgen Rays, has been done by means of the 18" (App's Newton) Coils, which I have found to be in every way reliable.

WILLIAM WEBSTER, Esq., says:—"The 18" Coil you supplied me with is giving every satisfaction, and I have obtained some wonderful phenomena with it. I shall be able to recommend your apparatus above all others that I have tried."

Sir LERKINS P. GLENN, Esq., says:—"I am very pleased with the new Coil, which works splendidly, giving the full 'x' Spark with only 5 to 9 amperes. It is thus a far more efficient machine than the 'x' for the amount of current used. I do not find the platinum burn very much."

WILSON NOBLE, Esq., says:—"I am delighted with the 18" Coil. It works extraordinarily smoothly."

SOLE MAKERS

NEWTON & CO.,
3 FLEET STREET, LONDON.

New Pattern Wimshurst Machines

THE GLASS PLATES ARE *WITHOUT* BRASS SECTORS.

The Spark is much improved in length and power.

By using discharging balls of a new pattern, the reversing of the current is prevented, and the Machine, which has been simplified and reduced in price, is the Best and Cheapest in the Market.

A—College Form, on polished mahogany base, with two 16 inch Plates, and four Leyden Jars, £25.

B—Iron Frame Form, with two 16-inch Plates and two Leyden Jars, £23 10s.

N.B.—This instrument is the strongest, neatest, and most powerful ever offered at the price.

C—School Form, with two 16 inch Plates and two Leyden Jars, £22 10s.

SCHOOL OF SCIENCE RESEARCH SCHOLARSHIPS

- (Founded by the late 1. Aubrey Bowen, Esq., of Melbourne, Australia.)
- (a) TWO BOWEN SCHOLARSHIPS in ENGINEERING, each of the value of about £60
 - (b) ONE BOWEN SCHOLARSHIP in METALLURGY, of the value of about £60
 - (c) THREE PRINCELEY SCHOLARSHIPS in CHEMISTRY, each of the value of about £50

The object of these SCHOLARSHIPS is to encourage Higher Work and Research in Scientific Professional Engineering and in Chemical and Metallurgical Science.

Applications, supported by details of educational training and references by former Teachers and others, should be sent to the REGISTRAR on or before June 11, 1898. The Awards will be made in September next, and the Scholarships will be payable during the Session 1898-99.

Further particulars may be obtained on application to the REGISTRAR.

BEDFORD COLLEGE, LONDON (FOR WOMEN),

YORK PLACE, BAKER STREET, W.

Principal: Miss F. M. HURD BATT

Session 1897-98

The latter Half Term begins on THURSDAY, MAY 26

ENTRANCE SCHOLARSHIPS

One Prefect Scholarship in Science, natural & artificial, and one Countess Scholarship in Arts, amounting to £500, each payable for three years, will be awarded on the result of the Examination to be held at the College on June 28 and 29.

Names to be sent to the Principal not later than June 15.

LUCY F. KUSSELL, Honorary Secretary

CIVIL SERVICE COMMISSION.

FORTHCOMING EXAMINATION

JUNIOR ASSISTANT in the Art Branch of the South Kensington Museum (Class A).

The date specified is the latest at which application can be received. It may be made on forms to be obtained with particulars from the SECRETARY, Civil Service Commission, London S.W.

MCGILL UNIVERSITY, MONTREAL.

CHAIR OF PHYSICS

The Board of Governors is prepared to receive applications for one of the W. C. McDonald Chairs of Physics, vacant by the recent appointment of Prof. Callender, M.A., F.R.S., to the Queen's Chair of Physics in University College, London. Salary \$4,000 per annum.

Applications accompanied by a testimonial which candidates may desire to submit, should reach the undersigned on or before June 25 next.

W. VAUGHAN, Secretary, McGill University, Montreal

MCGILL UNIVERSITY, MONTREAL.

CHAIR OF ELECTRICAL ENGINEERING

The Board of Governors is prepared to receive applications for the W. C. McDonald Chair of Electrical Engineering. Salary, not less than £2,000 dollars per annum.

Applications, accompanied by any testimonials which candidates may desire to submit, should reach the undersigned on or before June 25 next.

W. VAUGHAN, Secretary, McGill University, Montreal

MERCHANT VENTURERS' TECHNICAL COLLEGE, BRISTOL

JUNIOR ASSISTANT in METALLURGY and CHEMISTRY required in September. Salary £150 a year, increasing to £200.

Candidates must send in their applications not later than May 31, and must state that they have read the particulars as to the Post, which can be obtained from the REGISTRAR on application.

OWENS COLLEGE, MANCHESTER.

The Senate are prepared to appoint an ASSISTANT LECTURER and DEMONSTRATOR in BIOLOGY. The salary will be £200 per annum, and the Demonstrator will be expected to enter on his duties on September 30 next.

Applications, with testimonials, should be addressed to the REGISTRAR, not later than June 10, from whom a detailed statement of the duties, &c., may be obtained.

S. CHAFFERS, Registrar

UNIVERSITY COLLEGE, SHEFFIELD

PHYSIOLOGY

The Council intend to appoint a LECTURER in PHYSIOLOGY.

Particulars to be obtained from the REGISTRAR.

Applications must be received by June 11.

The Rt. Hon. the Earl of CRAWFORD, K.T., F.R.S., Chairman
The Rt. Hon. Lord Castletown | Hugh Esat Harrison
The Hon. R. Brougham | Francis Ince
Robert Hammond | William O'Smith

Affords a Theoretical and Practical Training, and qualifies the Sons of Gentlemen for Appointments in Mechanical and Electrical Engineering. After the Preliminary Training in Theory at the Institution, students go through a Practical Course, first in the Mechanical Engineering Works and subsequently in the Electrical Works, the Institution being associated with over 50 leading Firms and Engineers for this purpose. They are thus brought directly into association with prominent Companies and Firms, and secure an introduction to the Profession under the most favorable auspices. APPOINTMENTS HAVE BEEN SECURED FOR OVER 50 PER CENT OF THE STUDENTS who have completed their Course since the foundation of the Institution, and applications continue to be received for competent men. Prospective on application.

HEAD OFFICE

6 St. Andrew Square, EDINBURGH.

MUTUAL ASSURANCE with MODERATE PREMIUMS.

THE PREMIUMS are so moderate that an Assurance of £1200 or £1250 may generally be secured from the first for the yearly payment which usually would assure (with profits) £1000 only—equivalent to an immediate Bonus of 20 to 25 %

THE WHOLE SURPLUS goes to the Policyholders, on a system at once safe and equitable—no share being given to those by whose early death there is a loss

Examples of Premium for £100 at Death, with Profits

AGE.	30*	35	40	45	50	55
DURING LIFE,	£2 18	£2 10	£2 14	£3 5	£4 17	£5 11
25 PAYMENTS,	2 13 0	2 17 0	3 4 8	3 14 0	4 8 7	5 6 11
35 PAYMENTS,	3 12 1	3 18 0	4 5 8	4 16 2	5 11 6	6 9 11

*A person of 30 may secure £1000 at death by a yearly payment, during life, of £22 18s., which would in most Offices secure (with profits) £2000 only. Or he may secure £1000 by 25 payments of £28 10s., being thus free of payment before age 55

THE SURPLUS at last DIVISION (1894) was £1,423,000. More than one half of the Members who died during the last septennial period were entitled to Bonuses which, notwithstanding that the premiums do not as a rule exceed the non-profit rates of other Offices, were on the average equal to an Addition of about 50 per cent. to the Policies which participated

ACCUMULATED FUNDS, £10,000,000.

ARRANGEMENTS IN RE SURETIES, NON-FOREIGN, LOANS ON POLICIES, IMMEDIATE PAYMENT OF CLAIMS, FREE RESIDUAL, &c are specially liberal

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument invented for Survey Work in Mountainous Districts, and for Military or Rapid Surveys

The Photo Theodolite automatically records on the photograph all, or nearly all, the data necessary for the reduction of the photographs, including the Magnetic bearings,—thus considerably reducing the time spent and the risk of error in the interpretation of the photographs

The Instrument is fitted with an Aluminium Body, 6 in Azimuthal Circle, reading with Vernier to one minute of arc, 4 in Compass, divided to half degrees Telescope with erect and inverting Eyepieces, rapid Rectilinear Lens with Iris Diaphragm and Colour Screen, six double dark Slides in Mahogany Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description of the Instrument sent free on application

WHAT IS LIFE?
Or, WHERE ARE WE? WHAT ARE WE?
WHENCE DID WE COME?
AND WHITHER DO WE GO?

By **FREDERICK HOVENDEN,**
F.L.S., F.G.S., F.R.M.S.
(ASSISTED BY EMINENT SPECIALISTS),
With many Illustrations.

PREVIEWS OPINIONS

"We recommend our readers to peruse this work dispassionately and to form their own opinions, and they will, we imagine, be largely assisted by absence of prejudice. It would be futile to disguise the fact that in the work, as a whole, the author represents the tendency of modern thought among thinking people."—*Science Gossip*

"Mr. Hovenden is an audacious and fascinating author. His fascination arises from the magnitude of his subjects, and the unconventional, unpedantic manner in which he treats them; his audacity consists in his assumed emancipation from authority and scientific tradition."—*Manchester Courier*

"There is no need to weary the reader with examples of his grotesque equations—or of his puzzle he ideal protests against multiplying specific heat by atomic weight, which nobody outside Colney Hatch ever attempted to do."—*Leader in Liverpool Daily Post*

NOTE—See letter from the author to the above paper, March 9, 1898, p. 10, and "May I refer you to *Darwin's Mammals: Elementary Treatise on Heat*, 1888, page 30, for the Table of 'Specific Heats' multiplied by 'Atomic Weights'—almost all text books have this Table."

"The aim of the book is to throw, as it were, a searchlight on the pitiable and impenetrable darkness that prevails in regard to the study of nature, and to solve the mystery of the unknowable." Simplicity rather than subtlety marks the analysis of his subject, and not at any time is his phraseology enigmatical or technically obscure. While his arguments are based on cases stated, he is not so arrogant and dogmatic as to assert that on the evidence he adduces he is entitled to a verdict of 'proven'—*Belfast News Letter*

"As regards his scientific views, there is much that is true, for he has hewed largely and carefully."—*Standard*
"There is no doubt that the enlightened ideas set forth in the volume cannot but relieve the burden of a mind borne down by superstition."—*Scotsman*

CHARLES GRIFFIN & CO.'S LIST.

VOL. I NOW READY, COMPLETE IN ITSELF, Price 14s

In large 8vo, 160 pages, Cloth, with numerous Illustrations

TECHNICAL MYCOLOGY. the Utilization

of Micro Organisms in the Arts and Manufactures. A Practical Handbook on Fermentation and Fermentative Processes for the use of Brewers and Distillers, Analysts, Technical and Agricultural Chemists, and all interested in the Industries dependent on Fermentation. By Dr. FRANZ LAFAR, Professor of Fermentation Physiology and Bacteriology in the Technical High School, Vienna. With an Introduction by Dr. EMIL CHR. HANSEN, Principal of the Carlsberg Laboratory, Copenhagen. Translated by CHARLES F. C. SALTER. In Two Volumes, sold separately.

*The extraordinary roles played by Micro organisms in Brewing and Distilling—in the Manufacture of Sugar, of Vinegar, and Acetic Acid—in Tanning and Tobacco Manufacture—in Agricultural Industries and the Processes connected with the Dairy—Smearing of Cheese, Cheese Ripening, &c.—combine to make Dr. Lafar's text-book one of great value and interest to a very wide circle of readers. It is hoped that both Volumes of the English version will be issued during 1898.

BY PROFESSORS J. J. THOMSON AND POYNTING

In large 8vo Fully Illustrated

A TEXT-BOOK OF PHYSICS

Comprising PROPERTIES OF MATTER, SOUND, HEAT, MAGNETISM AND ELECTRICITY, AND LIGHT. BY J. H. POYNTING, Sc.D., F.R.S., Late Fellow of Trinity College, Cambridge. Professor of Physics, Mason College, Birmingham, and J. J. THOMSON, M.A., F.R.S., Fellow of Trinity College, Cambridge. Professor of Experimental Physics in the University of Cambridge.

*PUBLISHERS' NOTE.—It is intended that this important and long expected treatise shall be issued in separate Volumes, each complete in itself, at regular intervals, beginning with "SOUND," now at Press.

JAS. J. HICKS,

8, 9 & 10 HATTON GARDEN, LONDON,

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special construction, and a simple and accurate arterial pressure gauge. It is marvelously sensitive, and consists of a metal tambour, the expansion of which is exhibited in a highly magnified form by means of an index or pointer which travels round a dial. This dial is graduated in millimetres of mercury. The armlet pump and pressure gauge, when not in use, fit conveniently into a leather case. By means of this instrument we believe that the arterial pressure can be taken in man as rapidly, simply, and accurately as the temperature can be taken with the clinical thermometer.

Price £5. Spare Bag and Tube, 5s.

The Instrument has a 5-in. Dial, and is packed in a neat morocco Case with Handle.
FULLER PARTICULARS ON APPLICATION

THE "NEW LAND" SERIES OF PRACTICAL HANDBOOKS.

FOR THE USE OF PROSPECTORS, EXPLORERS, SETTLERS, COLONISTS, & ALL INTERESTED IN THE OPENING UP AND DEVELOPMENT OF NEW LANDS.

EDITED BY

GRENVILLE A. J. COLE, M.R.I.A., F.G.S.,

Professor of Geology in the Royal College of Science for Ireland.

In large Crown 8vo, with Illustrations

VOL. I. PROSPECTING FOR MINERALS: a Practical Handbook. By S. H. ROBERT COLE, Esq., R.N., M. Inst. M.M., F.G.S., &c. With Illustrations. (Cloth, 5s.; Leather, 6s. 6d.)

GENERAL CONTENTS.—Introduction and Hints on Geology—The Determination of Minerals. Use of the Blow pipe, &c.—Rock forming Minerals and Non Metallic Minerals of Commercial Value. Rock Salt, Borax, Marbles, Lithographic Stone, Quartz and Opal, &c., &c.—Precious Stones and Gemstones—Stratified Deposits. Coal and Ores—Mineral Veins and Lodes—Irregular Deposits—Dynamites of Lodes. Faults, &c.—Alluvial Deposits—Noble Metals. Gold, Platinum, Silver, &c.—Lead, Mercury, Copper, Tin, Zinc, Iron, Nickel, &c.—Sulphur, Antimony, Arsenic, &c.—Combustible Minerals—Petroleum—General Hints on Prospecting—Glossary—Index.

"THIS ADMIRABLE LITTLE WORK, written with SCIENTIFIC ACCURACY in a CLEAR and LUCID style — *Mining Journal*."

VOL. II. FOOD SUPPLY. By ROBERT BRUCE, Agricultural Superintendent to the Royal Dublin Society. With many Engravings from Photographs illustrating the chief Breeds of Cattle, Sheep, Pigs, Poultry, &c. (Leather, 7s. 6d.)

VOL. III. NEW LANDS AND THEIR PROSPECTIVE ADVANTAGES. By HUGH ROBERT MILL, D.Sc., F.R.S.E., Librarian to the Royal Geographical Society.

VOL. IV. BUILDING CONSTRUCTION IN WOOD, STONE, AND CONCRETE. By JAS. LYON, M.A., Professor of Engineering in the Royal College of Science for Ireland, sometime Superintendent of the Engineering Department in the University of Cambridge, and J. TAYLOR, A.R.C.S.I.

"APPS-NEWTON" 18-inch INDUCTION COIL.

Many of the leading X-Ray workers are now using the 18' APPS-NEWTON COIL in preference to the smaller sizes, owing to its greater penetrating power in thick parts of the body, and shortness of exposure, and we are now making them for some of the principal Hospitals. A photograph through the body of an adult showing heart, ribs, collar-bone, shoulder-blades, &c., most clearly taken by Mr. Webster in 4 minutes with our 18' Coil, can be seen at
3 FLEET STREET

Dr. J. MACINTYRE, of Glasgow, says:—"My latest experimental work in instantaneous X-Ray photography and cinematographic records to show movements of the body by means of the Roentgen Rays, has been done by means of the 18' (Appes Newton) Coil, which I have found to be in every way reliable."

WILLIAM WEBSTER, Esq., says:—"The 18' Coil you supplied me with is giving every satisfaction, and I have obtained some wonderful phenomena with it. I shall be able to recommend your apparatus above all others that I have tried."

Sir GERVAS P. GUY, Bart., says:—"I am very pleased with the new Coil, which works splendidly, giving the full 18" spark with only 2 to 3 amperes. It is thus a far more efficient machine than the 10" for the amount of current used. I do not find the platinum burn very much. WILSON NOBLE, Esq., says:—"I am delighted with the 18' Coil. It works extraordinarily smoothly."

SESSION—1897-98

The Easter Half Term begins on THURSDAY, MAY 26

ENTRANCE SCHOLARSHIPS

One Pfeiffer Scholarship in Science, annual value £25, and one Courtald Scholarship in Arts, annual value 30 Guineas, each tenable for three years, will be awarded on the result of the Examination to be held at the College on June 26 and 27

Names to be sent to the PRINCIPAL, not later than June 15
LUCY J. RUSSELL, Honorary Secretary

ROYAL GEOGRAPHICAL SOCIETY.

The Anniversary Meeting will be held (by permission of the Senate) in the Hall of the University of London, Burlington Gardens, W., on Monday, May 24, at 3 p.m. Sir CLEMENT R. MARKHAM, K.C.H., F.R.S., President, in the Chair. During the Meeting the Council and Officers will be elected for the ensuing year, the Annual Report of the Council will be read, the President will give his Address, and the Gold Medal and other Awards of the Society will be presented.

The Annual Dinner of the Society will be held on the evening of the Anniversary Meeting, at the Hotel Cecil, at 7 p.m. Dinner charge £4 12 friends of fellows are admissible to the Dinner.

ROYAL INSTITUTION OF GREAT BRITAIN,

ALBEMARLE STREET, PICCADILLY, W.

J. ARTHUR THOMSON, Esq., M.A., Lecturer on Biology School of Medicine, Edinburgh, will on Saturday next, May 22, at three o'clock, deliver the First of Two Lectures on "The Biology of Spring."

Subscription to this Course, Half a Guinea

CIVIL SERVICE COMMISSION. FORTHCOMING EXAMINATION

JUNIOR ASSISTANT in the Arts Branch of the South Kensington Museum (18-25) June 1

The date specified is the latest at which applications can be received. They must be made on forms to be obtained from the particulars, from the SECRETARY, Civil Service Commission, London, S.W.

INSTRUCTION IN PURE CULTIVATION OF YEAST.

According to HANSEN'S Methods

(Courses for Beginners, as well as for Advanced Students, in Physiology and Technology of Fermentation—Biological Analysis of Yeast. Manuals—Dr. Chr. Hansen's "Practical Studies in Fermentation," London (Spain), 1896; Alfred Jørgensen's "Micro-organisms and Fermentation," London (F.W.), 1897.

Further Particulars on application to the Director, ALFRED JØRGENSEN, The Laboratory, Copenhagen V.

MASON UNIVERSITY COLLEGE, BIRMINGHAM

FACULTY OF SCIENCE
RUSSELL SCHOLARSHIPS

(Founded by the late F. Aubrey Bowen, Esq., of Melbourne, Australia)

(a) TWO BOWEN SCHOLARSHIPS IN ENGINEERING, each of the value of about £200

(b) ONE BOWEN SCHOLARSHIP IN METALLURGY, of the value of about £200

(c) THREE PRINGLEY SCHOLARSHIPS IN CHEMISTRY, each of the value of about £200

The object of these SCHOLARSHIPS is to encourage Higher Work and Research in Scientific Professional Engineering and to Chemical and Metallurgical Science.

Applications, supported by details of educational training and references to former Teachers and others, should be sent to the REGISTRAR on or before June 11, 1898. The Awards will be made in September next, and the Scholarships will be tenable during the Session 1898-99.

Further particulars may be obtained on application to the REGISTRAR

MASON UNIVERSITY COLLEGE, BIRMINGHAM

LECTURER ON TECHNICAL ELECTRICITY

The Council invite APPLICATIONS for the above APPOINTMENT, vacant by the Resignation of Mr. R. H. Housman, M.I.E.E.

Applications, accompanied by Four Copies of Testimonials, should be sent to the undersigned, not later than Monday, June 20

The Candidate elected will be required to enter upon his duties on October 1, 1898

Further particulars may be obtained from

GEO. H. MORLEY, Registrar

UNIVERSITY OF GLASGOW.

EXAMINERSHIP IN PHYSICS

The University Court of the University of Glasgow will shortly proceed to appoint an Additional Examiner in Physics for Degrees in Medicine and Science

The Appointment will be for three years from 1st October next, at an annual fee of £50

Candidates should lodge twenty copies of their Application and Testimonials with the undersigned on or before 1st June next

ALAN L. CLAPPES ROUN, Secretary of the Court
91 West Regent Street, Glasgow

McGILL UNIVERSITY, MONTREAL.

CHAIR OF PHYSICS

The Board of Governors is prepared to receive applications for one of the W. C. McDonald Chairs of Physics vacant by the recent appointment of Prof. Callender, M.A., F.R.S., to the Queen's Chair of Physics in University College, London. Salary, \$5,000 per annum

Applications, accompanied by any testimonials which Candidates may desire to submit, should reach the undersigned on or before June 20 next

W. VAUGHAN, Secretary, McGill University, Montreal

McGILL UNIVERSITY, MONTREAL.

CHAIR OF ELECTRICAL ENGINEERING

The Board of Governors is prepared to receive applications for the W. C. McDonald Chair of Electrical Engineering. Salary, not less than 2000 dollars per annum

Applications, accompanied by any testimonials which Candidates may desire to submit, should reach the undersigned on or before June 20 next

W. VAUGHAN, Secretary, McGill University, Montreal

OWENS COLLEGE, MANCHESTER.

The Senate are prepared to appoint an ASSISTANT LECTURER and DEMONSTRATOR in BOTANY. The stipend will be £250 per annum, and the Demonstrator will be expected to enter on his duties on September 20 next

Applications, with Testimonials, should be addressed to the REGISTRAR, not later than June 10, from whom a detailed statement of the duties, &c., may be obtained

S. CHIFFERS, Registrar

MERCHANT VENTURERS' TECHNICAL COLLEGE, BRISTOL

JUNIOR ASSISTANT for METALLURGY and CHEMISTRY required in September. Salary £250 a year, increasing to £400

Candidates must send in their applications not later than May 31, and must state that they have read the particulars as to the Post, which can be obtained from the REGISTRAR on application

MR. ADAM SEDGWICK'S NEW ZOOLOGY
STUDENT'S TEXT-BOOK OF ZOOLOGY
 Vol. I.—PROTOZOA TO CHARTOGNATHA. By ADAM
 SEDGWICK, K. Fellow and Tutor of Trinity College, Cambridge,
 and Reader of Animal Morphology in the University of Cambridge. With
 472 Illustrations. 15s. *14th day*
First Review—"It is thoroughly up to date, and yet it is not broken
 with the past. Mr. Sedgwick is so experienced a teacher, and has himself
 contributed so much towards the existing knowledge of zoology, that the
 student can entirely trust himself to his guidance." *Daily Chronicle*

**THE BRIDGES-LEE
PHOTO-THEODOLITE**

The most perfect instrument
 invented for Survey Work in
 Mountainous Districts, and for
 Military or Rapid Surveys

The Photo Theodolite
 automatically records
 on the photograph all,
 or nearly all, the data
 necessary for the reduc-
 tion of the photographs,
 including the Magnetic
 bearings,—thus con-
 siderably reducing the
 time spent and the risk
 of error in the interpretation of
 the photographs

The instrument is fitted with
 an Aluminium Body, 6 in
 Azimuthal Circle, reading with
 Vernier to one minute of arc,
 4 in Compass, divided to half
 degrees. Telescope with erect
 and inverting Lenses, rapid
 Rectilinear Lens with Iris Dia-
 phragm and Colour screen, six double dark Slides in Mahogany
 Case, with Stand complete, £45.

VOLUME I NOW READY

A SYSTEM OF MEDICINE. By many Writers. Edited by THOMAS CLIFFORD ALLBUIT, M.A., M.D., LL.D., F.R.C.P., &c. Volume V DISEASES OF THE RESPIRATORY SYSTEM, DISEASES OF THE CIRCULATORY SYSTEM. Demy 8vo, 25s net

VOLUME II NOW READY

ELECTRO-PHYSIOLOGY. By W. BIEDERMANN, Professor of Physiology in Jena. Translated by FRANCES A. WELBY. With One Hundred and Forty Nine Figures. Vol. II 8vo, 17s net

NATURE "Students of physiology who find, as many do, their ignorance of German to be an embarrassing obstacle in their reading, ought to be grateful to Miss Welby for her skilful translation of Prof. Biedermann's 'Electrophysiology.' The value of the book consists chiefly in this—that it is a faithful record of the results yielded by the researches of the last half century in the field of inquiry to which it relates. On the whole Miss Welby has given the sense of her author with great care and accuracy."

BY THE RIGHT HON. LORD FARRER

STUDIES IN CURRENCY, 1898; or, Inquiries into certain Modern Problems connected with the Standard of Value and the Medium of Exchange. By the Right Hon. Lord FARRER. Demy 8vo, 12s 6d net

"APPS-NEWTON" 18-inch INDUCTION COIL.

Many of the leading X-Ray workers are now using the 18" APPS-NEWTON COIL in preference to the smaller sizes, owing to its greater penetrating power in thick parts of the body, and shortness of exposure, and we are now making them for some of the principal Hospitals. A photograph through the body of an adult showing heart, ribs, collar-bone, shoulder-blades, &c., most clearly taken by Mr Webster in 3 minutes with our 18" Coil, can be seen at

9 FLEET STREET

Dr J. MACINTYRE, of Glasgow, says:—"My latest experiment in work in instantaneous X-Ray photography and cinematographic records to show movements of the body by means of the Roentgen Rays, has been done by means of the 18" (Appsi Newton) Coils, which I have found to be in every way reliable."

WILLIAM WEBSTER, Esq., says:—"The 18" Coil you supplied me with is giving every satisfaction, and I have obtained some wonderful phenomena with it. I shall be able to recommend your apparatus above all others that I have tried."

Sir GERVAIS P. GYAN, Bart., says:—"I am very pleased with the new Coil, which works splendidly, giving the full 18" Spark with only 8 to 9 amperes. It is thus a far more efficient machine than the 16" for the amount of current used. I do not find the platina burn very much."

WILSON NOBLE, Esq., says:—"I am delighted with the 18" Coil. It works extraordinarily smoothly."

MANUFACTURED BY
NEWTON & CO.,
3 FLEET STREET, LONDON.

NOW READY. 3RD EDITION

CHEMICAL HANDICRAFT.

A CLASSIFIED AND DESCRIPTIVE CATALOGUE OF CHEMICAL APPARATUS AND REAGENTS, suitable for the performance of CLASS Experiments, for every Process of Chemical Research, and for Chemical Testing in the Arts. Accompanied by copious Notes, explanatory of the construction and use of the Apparatus.

In One Large Volume, Royal 8vo, 440 pp., Illustrated by 1500 Engravings. Price 3s. Post free.

This Edition has been entirely rewritten up to date, and is illustrated by many hundreds of new Engravings specially prepared from Photographs of the Apparatus.

The prices have been thoroughly revised, and the book forms the **MOST COMPLETE and CHEAPEST CATALOGUE of MODERN APPARATUS and REAGENTS extant**

**JOHN J. GRIFFIN & SONS, 12
22 GARRICK STREET, LONDON, W.C.**

NALDER BROS. & CO., LTD. 16 RED LION STREET, LONDON, E.C.

AYRTON-MATHER UNIVERSAL SHUNT BOX.

Does not need adjusting for each instrument, but can be used instantaneously for Galvanometers of any resistance. No plugs to get lost. Multiplying powers: 1, 10, 100, 1000, 10000. This instrument also makes a convenient form of Potentiometer.

Price £3 15s

Write for Catalogue (Cable Address: "NEGRETTI, LONDON")

ENGINEERING AND CHEMISTRY CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Instruction at the Institute's CENTRAL TECHNICAL COLLEGE (Exhibition Road) are for Students not under 16 years of age, those at the Institute's TECHNICAL COLLEGE, FINSBURY, are of an Intermediate Grade for students not under 14 years of age. The Entrance Examinations to both Colleges are held in September, and the Sessions commence in October. Particulars of the Entrance Examinations, Scholarships, Fees, and Courses of study, may be obtained from the respective Colleges, or from the Head Office of the Institute, Gresham College, Basinghall Street, E.C.

CITY AND GUILDS CENTRAL TECHNICAL COLLEGE (EXHIBITION ROAD, S.W.)

A College for higher Technical Instruction for Students not under 16 preparing to become Civil, Mechanical or Electrical Engineers, Chemists and other Manufacturers, and Teachers. Fees for a full Associateship Course, £25 per Session. Professors—

Civil and Mechanical Engineering W. C. UNWIN, F.R.S., M.Inst.C.E.
Physics and Electrical Engineering W. F. AYRTON, F.R.S., Past Pres.
Chemistry H. E. ARMSTRONG, Ph.D., LL.D., F.R.S.
Mechanics and Mathematics O. HENCKS, Ph.D., LL.D., F.R.S.

CITY AND GUILDS TECHNICAL COLLEGE, FINSBURY (1 FORD STREET, CITY ROAD, E.C.)

Provides Courses of Intermediate Instruction for Day Students not under 14 years of age, preparing to enter Engineering and Chemical Industries. Fees, £15 per Session. Professors—

Physics and Electrical Engineering S. P. THOMSON, D.Sc., F.R.S.
Mechanics W. I. DALRY, M.A., B.Sc., M.I.M.E.
Chemistry R. MELDOLA, F.R.S., F.I.C.

JOHN WATNEY, Hon. Secretary

City and Guilds of London Institute,
Gresham College, Basinghall Street, F.C.

THE DAVY FARADAY RESEARCH LABORATORY OF THE ROYAL INSTITUTE.

DIRECTORS

The Right Hon. LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.S.

Professor DEWAR, M.A., LL.D., F.R.S.

SUPERINTENDENT OF THE LABORATORY

DR. ALEXANDER SCOTT, M.A., D.Sc.

This Laboratory, founded by Dr. Ludwig Mond, F.R.S., as a Memorial to Davy and Faraday for the purpose of promoting original research in Pure and Physical Chemistry, will be open during the following Terms—

Michaelmas Term—Monday, October 1, to Saturday, December 17.
Lent Term—Monday, January 9, to Saturday, March 25.
Easter Term—Monday, April 12, to Saturday, July 29.

Under the Deed of Trust, workers in the Laboratory are entitled, free of charge, to Gas, Electricity and Water, in as far as available, and, at the discretion of the Directors, to the use of the apparatus belonging to the Laboratory, together with such materials and chemicals as may be authorised.

All persons desiring to be admitted as workers, must send evidence of scientific training, qualification, and previous experience in original research, along with a statement of the nature of the investigation they propose to undertake.

Candidates must apply for admission during the course of the preceding Term.

Forms of Application can be had from the ASSISTANT SECRETARY, Royal Institution, Albemarle Street, W.

ELECTRICAL ENGINEERING.

The ELECTRICAL STANDARDIZING, TESTING, and TRAINING INSTITUTION, 8 CHALKING CROSS ROAD, LONDON.
(Proprietors—Syndicate of Electrical Engineers, Ltd.)

BOARD OF CONTROL

The Rt. Hon. the Earl of CRAWFORD, K.T., F.R.S., Chairman
The Rt. Hon. Lord Cussetown
The Hon. R. Hougham
Robert Hammond
Hugh Earl Harrison
Francis Fox
William O. Smith

Affords a Theoretical and Practical Training, and qualifies the Sons of Gentlemen for Appointments in Mechanical and Electrical Engineering. The Preliminary Training in Theory at the Institution, Students go through a Practical Course first in the Mechanical Engineering Works and subsequently the Electrical Works, the Institution being associated with over 30 leading Firms and Engineers for this purpose. They are thus brought directly into association with prominent Companies and Firms, and so are an introduction to the Profession under the most favourable auspices. APPOINTMENTS HAVE BEEN SECURED FOR OVER 80 PER CENT OF THE STUDENTS who have completed their Course since the foundation of the Institution and applications continue to be received for competent men. Prospectus on application.

THE ELECTRICAL AND GENERAL ENGINEERING COLLEGE, AND EXPERIMENTAL ENGINEERING WORKS,

2 and 4 PENYVERN ROAD, EARL'S COURT,
LONDON, S.W.

Trains Students for Electrical, Mechanical, and Mining Engineering. Develops Electrical and Mechanical Talents. Constructs Experimental and Special Machinery and Models to Specification.

MASON UNIVERSITY COLLEGE, BIRMINGHAM

FACULTY OF SCIENCE
RESIDUAL SCHOLARSHIPS

(Founded by the late J. Aulrey Mason, Esq., of Mollins, Aulstrey).
(a) TWO RESIDUAL SCHOLARSHIPS in ENGINEERING, each of the value of about £60.
(b) ONE RESIDUAL SCHOLARSHIP in MECHANICS, of the value of about £60.
(c) THREE RESIDUAL SCHOLARSHIPS in CHEMISTRY, each of the value of about £60.

The object of these SCHOLARSHIPS is to encourage Higher Work and Research in Scientific Profession in Engineering and in Chemical and Metallurgical Industries.

Applications, supported by details of educational training and references to former Teachers and others, should be sent to the Registrar on or before June 11, 1898. The Awards will be made in September next, and the Scholarships will be payable during the Session 1898-99.

Further particulars may be obtained on application to the Registrar.

BEDFORD COLLEGE, LONDON (FOR WOMEN),

YORK PLACE, BAKER STREET, W.

Principal—Miss ETHEL HURBATT

SESSION 1897-98

The Winter Half Term begins on THURSDAY, MAY 26

FINANCIAL SCHOLARSHIPS

One Pfeiffer Scholarship in Science, annual value £48, and one Courtauld Scholarship in Arts, annual value 50 Guineas, each tenable for three years will be awarded on the result of the Examination to be held at the College on June 28 and 29.

Names to be sent to the PRINCIPAL, not later than June 15.

LUCY J. RUSSELL, Honorary Secretary

INSTRUCTION IN PURE CULTIVATION OF YEAST.

According to HANSEN'S Methods

Courses for Beginners, as well as for Advanced Students, in Physiology and Technology of Fermentations—Biological Analysis of Yeast.

Manuals—R. Chr. Hansen "Practical Studies in Fermentation" (London, 1896). Alfred Jørgensen "Micro-organisms and Fermentation" (London, F. W. Lyon, 1897).

Further Particulars on Application to the Director, ALFRED JØRGENSEN, The Laboratory, Copenhagen, V.

WANTED, by a large Firm of Malsters and

Agricultural Merchants, a young Gentleman qualified to make Analyses of Feeding Cakes, Manures, &c. Preference will be given to one possessing knowledge of the Seed Trade—Address, stating qualifications and salary required, SECRETARY, FITTIS, SON, AND KING, LTD., Plymouth.

MASON UNIVERSITY COLLEGE, BIRMINGHAM

LECTURER ON TECHNICAL ELECTRICITY

The Council invite APPLICATIONS for the above APPOINTMENT, vacant by the Resignation of Mr. R. H. Housman, M.I.E.E. Applications, accompanied by Four Copies of Testimonials, should be sent to the undersigned, not later than Monday, June 5.

The Candidate elected will be required to enter upon his duties on October 1, 1898.

Further particulars may be obtained from

GEO. H. MORLEY, Registrar.

EAST SUFFOLK COUNTY COUNCIL.

TECHNICAL INSTRUCTION COMMITTEE

The Committee are prepared to receive applications for the post of SCIENCE TEACHER. The Salary will be £200 per annum. Applicants must have a thorough Practical and Theoretical knowledge of Machine Construction, and of at least one of the following Sciences—Mechanics, Steam, Mathematics, Electricity.

Applications must be made upon forms to be obtained from the undersigned upon receipt of a stamped directed envelope.

W. F. WATKINS, Organising Secretary.

20 Butter Market, Ipswich.

THE DURHAM COLLEGE OF SCIENCE,

NEWCASTLE-UPON-TYNE.

The Council invite applications for the post of ASSISTANT LECTURER and DEMONSTRATOR in PHYSICS.

The stipend attached to the appointment is £150 per annum, rising to £170 per annum. Duties will commence on October 1 next.

Applications and testimonials must be sent on or before June 14, to the undersigned, from whom further particulars may be obtained.

H. F. STOCKDALE, Secretary.

THE DURHAM COLLEGE OF SCIENCE,

NEWCASTLE-UPON-TYNE.

The Council invite applications for the LEADERSHIP in ART, INDUSTRIAL CHEMISTRY, which will become vacant in the middle of August. The stipend attached to the post is £150 per annum.

Applications with testimonials should be sent in a letter, dated June 15, 1898, to the undersigned, from whom further particulars may be obtained.

H. F. STOCKDALE, Secretary.

OWENS COLLEGE, MANCHESTER

The Senate are prepared to appoint an ASSISTANT LECTURER and DEMONSTRATOR in BIOLOGY. The stipend will be £200 per annum, and the Demonstrator will be expected to enter on his duties on September 1 next.

Applications, with Testimonials, should be addressed to the REGISTRAR, not later than June 10, from whom a detailed statement of the duties, &c., may be obtained.

S. CHAFFERS, Registrar.

OWENS COLLEGE, MANCHESTER.

The Senate are prepared to appoint, for a period of three years, a JUNIOR DEMONSTRATOR in PHYSICS, who will be required to enter on his duties on September 1 next. Stipend £150.

Applications should be addressed, not later than June 10, to the REGISTRAR, from whom additional statement of duties, &c., may be obtained.

S. CHAFFERS, Registrar.

UNIVERSITY COLLEGE, SHEFFIELD.

PHYSIOLOGY

The Council intend to appoint a LECTURER in PHYSIOLOGY.

Particulars to be obtained from the REGISTRAR.

Applications must be received by June 11.

F. SNODGRASS, Registrar.

VICTORIA UNIVERSITY

THE YORKSHIRE COLLEGE, LEEDS.

Applications will be received up to June 20 for the appointment of Demonstrator of Physiology, Salary, £150. Particulars may be obtained from the COLLEGE SECRETARY.

CIVIL SERVICE COMMISSION.

FORTHCOMING EXAMINATION

JUNIOR ASSISTANT in the Art Branch of the South Kensington Museum (18-23, June).

The date specified is the latest at which applications can be received. They must be made on forms to be obtained, with particulars, from the REGISTRAR, Civil Service Commission, London, S.W.

SKILLED ATTENDANT in Zoological

Laboratory and Museum Preparation Room WANTED, one who has experience and can mount and label preparations required. Applying age, present wages, and references, to Prof. LANKESTER, The Museum, Oxford.

NATURAL HISTORY GALLERY

158 BROMPTON ROAD, LONDON.

Dealer in Rocks, Minerals, Fossils, and other Objects

of Scientific Interest.

Among Specimens of Rocks recently collected by Mr BUTLER are
Opbitic Olivine Dolomite with Labradorite. Phenocrysts and Mica Inset
from dykes, and Olivine Basalt. Telsomory, Mill, Basalt, fresh and
altered, Calve Is., White Marble with Salite and Pink ditto with Horn
blende and Covellite and at contact with Gneiss, Trer, Hornblende
and coarse and fine grained Gneiss, Coll. Olivine Dolomite. Dykes and Scur
porphyritic Rhyolite. Fichtelberg, light plebeitic Granite with included
Onelia fragments, Quartzite, and the recently described Olivine Monzonite,
from near Ballachulish. Micro Sections of the above can be furnished.

MACMILLAN & CO.'S NEW BOOKS.

A TEXT-BOOK OF ENTOMOLOGY, including the Anatomy, Physiology, Embryology and Metamorphoses of Insects for use in Agricultural and Technical Schools and Colleges, as well as by the working Entomologist. By ALPHIUS S. PACKARD, M.D., Ph.D., Professor of Zoology and Geology, Brown University. Demy 8vo, 18s net

A TEXT-BOOK OF ZOOLOGY. By T. JEFFERY PARKER, D.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, N.Z., and WILLIAM A. HASWELL, M.A., D.Sc., F.R.S., Professor of Biology in the University of Sydney, N.S.W. In two Vols. With Illustrations. Medium 8vo, 36s net

SCIENCE PROGRESS—"The appearance of this important work, for which many of us have been eagerly waiting, will be hailed with pleasure. When we consider the difficulties under which these authors laboured, one in New Zealand the other in Sydney, the printers, publishers and artists in England, one can only marvel at the splendid work they have produced, one that will be useful both to the elementary and advanced student as well as to the teacher."

THE SUN'S PLACE IN NATURE. By Sir NORMAN LOCKYER, K.C.B., F.R.S., Ac. 8vo, 12s

OBSERVATORY—"The book, as giving an account of several years' work at the South Kensington Astrophysical Laboratory, and the Director's deductions therefrom, is certainly one to be read by every student of the science."

A SYSTEM OF MEDICINE. By many Writers. Edited by THOMAS CLIFFORD ALBUTT, M.A., M.D., LL.D., F.R.C.P., Ac. Volume V. DISEASES OF THE RESPIRATORY SYSTEM. DISEASES OF THE CIRCULATORY SYSTEM. Demy 8vo, 25s net

ELECTRO-PHYSIOLOGY. By W. BIEDERMANN, Professor of Physiology in Jena. Translated by FRANCIS A. WELBY. With One Hundred and Forty nine figures. Vol. II. 8vo, 17s net

NATURE—"Students of physiology who find, as many do, their ignorance of German to be an embarrassing obstacle in their reading, ought to be grateful to Miss Welby for her skilful translation of Prof. Biedermann's 'Electrophysiology'. The value of the book consists chiefly in this—that it is a faithful record of the results yielded by the researches of the last half century in the field of inquiry to which it relates. On the whole Miss Welby has given the sense of her author with great care and accuracy."

STUDIES IN CURRENCY, 1898; or, Inquiries into certain Modern Problems connected with the Standard of Value and the Media of Exchange. By the Right Hon. Lord FARRER. Demy 8vo, 12s 6d net

THE SCIENCE OF LAW AND LAW-MAKING: Being an Introduction to Law, a General View of its Forms and Substance, and a Discussion of the Questions of Codification. By R. FLOYD CLARKE, A.B., LL.B., of the New York Bar. Demy 8vo, 17s net

PRIMER OF PSYCHOLOGY. By EDWARD BRADFORD TITCHENER. Crown 8vo, 4s 6d

JAS. J. HICKS, 8, 9 & 10 HATTON GARDEN, LONDON.

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special
construction, and a simple and accurate arterial pressure gauge.
It is marvellously sensitive, and consists of a metal tambour,
the expansion of which is exhibited in a highly magnified form
by means of an index or pointer which travels round a dial.
This dial is graduated in millimetres of mercury. The armlet
pump and pressure gauge, when not in use, fit conveniently into
a leather case. By means of this instrument we believe that
the arterial pressure can be taken in man as rapidly, simply, and
accurately as the temperature can be taken with the clinical
thermometer.

Price £5. Spare Bag and Tube, 5s.

The Instrument has a 5-in. Dial, and is packed in a
neat morocco Case with Handle.

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"To the solid ground
Of Nature trusts the mind which builds for aye"—WORDSWORTH

No 1492, VOL 58]

THURSDAY, JUNE 2, 1898

[PRICE SIXPENCE

Registered as a Newspaper at the General Post Office.]

[All Rights are Reserved]

"APPS-NEWTON" 18-inch INDUCTION COIL.

Many of the leading X-Ray workers are now using the 18" APPS-NEWTON COIL in preference to the smaller sizes, owing to its greater penetrating power in thick parts of the body, and shortness of exposure, and we are now making them for some of the principal Hospitals. A photograph through the body of an adult showing heart, ribs, collar-bones, shoulder-blades, &c., most clearly taken by Mr Webster in 3 minutes with our 18" Coil, can be seen at
8 FLEET STREET

Dr J MACINTYRE, of Glasgow, says—"My latest experimental work in instantaneous X-Ray photography and cinematography records to show movements of the body by means of the Röntgen Rays, has been done by means of the 18" (App's Newton) Coil, which I have found to be in every way reliable."

WILLIAM WEBSTER, Esq., says—"The 18" Coil you supplied me with is giving every satisfaction, and I have obtained some wonderful phenomena with it. I shall be able to recommend your apparatus above all others that I have tried."

SIR GRIVAS P GYNN, Bart., says—"I am very pleased with the new Coil, which works splendidly, giving the full 18" spark with only 3 to 9 amperes. It is thus a far more efficient machine than the 10" for the amount of current used. I do not find the platinum burn very much."

WILSON NOBLE, Esq., says—"I am delighted with the 18" Coil. It works extraordinarily smoothly."

MANUFACTURED BY
NEWTON & CO.,

MACMILLAN & CO.'S NEW SCIENTIFIC WORKS.

VOLUME V NOW READY

A SYSTEM OF MEDICINE. By many Writers. Edited by THOMAS CLIFFORD ALLBUTT, M.A., M.D., LL.D., F.R.C.P., &c. Volume V DISEASES OF THE RESPIRATORY SYSTEM, DISEASES OF THE CIRCULATORY SYSTEM Demy 8vo, 25s. net.

Demy 8vo, 18s. net

A TEXT-BOOK OF ENTOMOLOGY, including the Anatomy, Physiology, Embryology and Metamorphoses of Insects for use in Agricultural and Technical Schools and Colleges, as well as by the working Entomologist. By ALPHIEUS S. PACKARD, M.D., Ph.D., Professor of Zoology and Geology, Brown University.

SCOTSMAN—"The anatomy, embryology, and metamorphoses of insects are treated with as much detail as will be required by the specialist outside of his own province, while the treatment is such as will keep the philosophical bearings of each fact before the reader. A remarkable feature of the work is the fulness of its references."

VOLUME II NOW READY

ELECTRO-PHYSIOLOGY. By W. BIEDERMANN, Professor of Physiology in Jena. Translated by FRANCES A. WELBY. With One Hundred and Forty nine Figures. Vol. II 8vo, 17s. net.

NATURE—"Students of physiology who find, as many do, their ignorance of German to be an embarrassing obstacle in their reading, ought to be grateful to Miss Welby for her skilful translation of Prof. Biedermann's 'Electrophysiology.' The value of the book consists chiefly in this—that it is a faithful record of the results yielded by the researches of the last half-century in the field of inquiry to which it relates. On the whole Miss Welby has given the sense of her author with great care and accuracy."

A TEXT-BOOK OF BOTANY. By Dr. E. STRASBURGER, Dr. FRITZ NOLL, Dr. H. SCHENCK, Dr. A. F. W. SCHIMPER. Translated from the German by H. C. PORTER, Ph.D., Assistant Instructor of Botany, University of Pennsylvania. With 594 Illustrations, in part Coloured. Medium 8vo 18s. net.

SCIENCE GOSPIP—"One of the most modern and carefully prepared works that has recently been submitted to botanists. The whole of the illustrations are carefully selected and well executed. . . . Sure to be largely in demand for both library and scholastic purposes."

THIRD EDITION, REVISED AND CORRECTED

THE MECHANICS OF MACHINERY. By ALEX. B. W. KENNEDY, LL.D., F.R.S., Emeritus Professor of Engineering and Mechanical Technology in University College, London, Member of the Institution of Civil Engineers, Honorary Life Member and past President of the Institution of Mechanical Engineers, &c. With numerous illustrations. Crown 8vo, 8s. 6d.

A TREATISE ON MAGNETISM AND ELECTRICITY. By ANDREW GRAY, LL.D., F.R.S., Professor of Physics in the University College of North Wales. In Two Volumes. Vol. I, Demy 8vo, 14s. net.

ELECTRICAL REVIEW—"The production of this work is creditable to the author, and to the distinguished school of physicists that trained him. The book is beautifully printed and got up, and will, no doubt, find a place on the shelves of all mathematical physicists."

AN ELEMENTARY COURSE OF PHYSICS. Edited by Rev. J. C. P. ALDOUS, M.A., Chief Instructor in M.S. *Britannica*, late Fellow of Jesus College, Cambridge. Demy 8vo, 7s. 6d. In Three Parts. Part I. MECHANICS, PROPERTIES OF MATTER, HYDROSTATICS, HEAT. By the Editor. 4s. 6d. Part II. WAVE MOTION, SOUND, LIGHT. By W. D. EGGER, M.A., Assistant Master, Eton College. 2s. 6d. Part III. MAGNETISM, ELECTRICITY. By F. K. BARRELL, M.A., B.Sc., &c. 2s. 6d. [*Britannica Series*]

NATURE—"The treatment of the various subjects is most lucid and thorough, and is evidently based on an intimate acquaintance with the requirements of students. Great pains have been taken to avoid looseness of statement, and the fact that some of the sections have had the advantage of the criticisms and suggestions of Lord Kelvin, Lord Rayleigh, and others, makes it a trustworthy book of reference. We believe it is destined to take a high place in our schools and colleges."

NOTES ON OBSERVATIONS. Being an Outline of the Methods used for Determining the Meaning and Value of Quantitative Observations and Experiments in Physics and Chemistry, and for Reducing the Results obtained. By SYDNEY LUPTON, M.A. Crown 8vo, 3s. 6d.

GUARDIAN—"A Earnest student, thinkers, and beginners in original research will be thankful for Mr. Lupton's modest volume. He has rigidly compressed and lucidly arranged a series of twenty-two little outline chapters, which cannot but be of service, whilst the eclectic notes will permit the reader indefinitely to expand the outlines. . . . Everywhere the Notes indicate careful weighing of words and selection of matter."

BY THE RIGHT HON. LORD FARKER

STUDIES IN CURRENCY, 1898; or, Inquiries into certain Modern Problems connected with the Standard of Value and the Media of Exchange. By the Right Hon. Lord FARKER. Demy 8vo, 12s. 6d. net.

DAILY NEWS—"The various chapters treat currency questions from so many points of view and with such fulness of knowledge, that the volume forms a really comprehensive treatise on monetary science."

Crown 8vo, 4s. 6d.

PRIMER OF PSYCHOLOGY. By EDWARD BRADFORD TITCHENER.

SCOTSMAN—"A handbook marked by so unusual skill in exposition as to be well worthy of the attention of all who are interested in its subject."

MACMILLAN & CO., LIMITED, LONDON.

ATWOOD MACHINE

Gives Accurate Results, Small Space required, Fastens to Wall, Length 4 to 9 Feet, Electric Release, Sliding Platforms, Weights and Overweights, Balanced Wheel, Levelling Arrangement. Graduated, £3 15s., not Graduated, £3 5s (nett)
This Machine gives first class results, and is to be depended upon

"To the solid ground
Of Nature trusts the mind which builds for aye"—WORDSWORTH

No 1493, Vol. 58]

THURSDAY, JUNE 9, 1898

[PRICE SIXPENCE.

Registered as a Newspaper at the General Post Office.]

[All Rights are Reserved]

"APPS-NEWTON" 18-inch INDUCTION COIL.

Many of the leading X-Ray workers are now using the 18" APPS-NEWTON COIL in preference to the smaller sizes, owing to its greater penetrating power in thick parts of the body, and shortness of exposure, and we are now making them for some of the principal Hospitals. A photograph through the body of an adult showing heart, ribs, collar-bones, shoulder-blades, &c., most clearly taken by Mr Webster in 3 minutes with our 18" Coil, can be seen at
8 FLEET STREET

Dr J MACINTYRE, of Glasgow, says:—"My latest experimental work in instantaneous X-Ray photography and cinematographic records to show movements of the body by means of the Roentgen Rays, is made done by means of the 18" (App's Newton) Coil, which I have found to be in every way reliable."

WILLIAM WEBSTER, Esq. says:—"The 18" Coil you supplied me with is giving every satisfaction, and I have obtained some wonderful phenomena with it. I shall be able to recommend your apparatus above all others that I have tried."

SIR GERVAS F. GUY, BART., says:—"I am very pleased with the new Coil, which works splendidly, giving the full 18" spark with only 8 to 9 amperes. It is thus a far more efficient machine than the 10" for the amount of current used. I do not find the platinum burn very much."

WILSON NORRIS, Esq., says:—"I am delighted with the 18" Coil. It works extraordinarily smoothly."

MANUFACTURED BY
NEWTON & CO.,
3 FLEET STREET, LONDON.

DIRECTORS—

The Right Hon. LORD RAYLEIGH, M.A., D.C.L.,
LL.D., F.R.S.

Professor DEWAR, M.A., LL.D., F.R.S.

SUPERINTENDENT OF THE LABORATORY
Dr. ALEXANDER SCOTT, M.A., D.Sc.

This Laboratory, founded by Dr. Ludwig Mond, F.R.S., as a Memorial of Davy and Faraday for the purpose of promoting original research in Pure and Physical Chemistry, will be open during the following Terms—

Michaelmas Term—Monday, October 3, to Saturday, December 17
Lent Term—Monday, January 9, to Saturday, March 25
Easter Term—Monday, April 17, to Saturday, July 2

Under the Deed of Trust, workers in the Laboratory are entitled, free of charge, to Gas, Electricity and Water, as far as available, and, at the discretion of the Directors, to the use of the apparatus belonging to the Laboratory, together with such materials and chemicals as may be authorized.

All persons desiring to be admitted as workers, must send evidence of scientific training, qualification, and previous experience in original research, along with a statement of the nature of the investigation they propose to undertake.

Candidates must apply for admission during the course of the preceding Term.

Forms of Application can be had from the ASSISTANT SECRETARY, Royal Institution, Albemarle Street, W.

ELECTRICAL ENGINEERING.

The ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTE, 4 CHARING CROSS ROAD, LONDON.
(Proprietors—Syndicate of Electrical Engineers, Ltd.)

BOARD OF CONTROL.

The Rt. Hon. the Earl of CRAWFORD, K.T., F.R.S., Chairman
The Rt. Hon. Lord Castletown Hugh Earl Harrison
The Hon. R. Brougham Francis Ince
Robert Hammond William O. Smith

Affords a Theoretical and Practical Training, and qualifies the Sons of Gentlemen for Appointments in Mechanical and Electrical Engineering. After the Preliminary Training in Theory at the Institution, Students go through a Practical Course, first in the Mechanical Engineering Works and subsequently the Electrical Works, the Institution being associated with over 50 leading Firms and Engineers for the purpose. They are thus brought directly into association with prominent Companies and Firms, and secure an introduction to the Profession under the most favourable auspices. APPOINTMENTS HAVE BEEN SECURED FOR OVER 10 PER CENT OF THE STUDENTS who have completed their Course since the foundation of the Institution, and applications continue to be received for competent men. Prospectus on application.

THE ELECTRICAL AND GENERAL ENGINEERING COLLEGE, AND EXPERIMENTAL ENGINEERING WORKS,

2 and 4 PENYVERN ROAD, EARL'S COURT,
LONDON, S.W.

Trains Students for Electrical, Mechanical and Mining Engineering.
Develops Electrical and Mechanical Patents.
Constructs Experimental and Special Machinery and Models to Specification.

BALLIOL COLLEGE, CHRIST CHURCH, AND TRINITY COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIPS AND EXHIBITIONS

A Combined Examination for Natural Science Scholarships and Exhibitions will be held by the above Colleges, beginning on TUESDAY, NOVEMBER 15, 1898.

Three Scholarships and two Exhibitions will be offered, the scholarships being worth £80 a year.

The Subjects for Examination will be Physics, Chemistry, and Biology, but Candidates will not be expected to offer themselves in more than two of these.

Particulars may be obtained by application to
Clarendon Church, Oxford. A. VERNON HARCOURT

UNIVERSITY OF LONDON, PRELIMINARY SCIENTIFIC AND INTERMEDIATE EXAMINATIONS IN BIOLOGY

LONDON HOSPITAL MEDICAL COLLEGE.

A Russian Class begins on Monday, June 20, at 10 a.m., and will be continued on Mondays and Tuesdays, 10-4, and on Wednesdays, 10-12 p.m., until the July examination.

Fees (including materials) to Students joining this Class, only £3 10s.

This Class is not confined to students of the Hospital.
MUNRO SCOTT, Warden.

BEDFORD COLLEGE, LONDON (FOR WOMEN),

YORK PLACE, BAKER STREET, W.

Principal—Miss K. H. HURLBATT

SCOTTISH PROVIDENT INSTITUTION.

HEAD OFFICE:

6 St. Andrew Square, EDINBURGH.

MUTUAL ASSURANCE with MODERATE PREMIUMS

The PREMIUMS are so moderate that an Assurance of £1200 or £1250 may generally be secured from the first for the yearly payment which usually would assure (with profits) £1000 only—equivalent to an immediate Bonus of 20 to 25 % The WHOLE SURPLUS goes to the Policyholders, on a system at once safe and equitable—no share being given to those by whose early death there is a loss

Examples of Premium for £100 at Death, with Profits

Age	30*	35	40	45	50	55
DURING LIFE	£2 18	£2 8 10	£2 14 9	£3 5 9	£4 17	£5 1 11
25 PAYMENTS	2 13 0	2 17 9	3 4 8	3 14 0	4 8 7	5 8 11
15 PAYMENTS	3 12 1	3 18 0	4 5 8	4 16 8	5 11 8	6 9 11

* A person of 30 may secure £1000 at death by a yearly payment, during life, of £20 15s., which would in most Offices secure (with profits) £2000 only. Or he may secure £1000 by 25 payments of £26 10s., being thus free of payment before age 55.

The SURPLUS at last Division (1894) was £1,423,000. More than one half of the Members who died during the last Septennial period were entitled to Bonuses which, notwithstanding that the premiums do not as a rule exceed the non profit rates of other Offices, were on the average equal to an Addition of about 50 per cent. to the Policies which participated

ACCUMULATED FUNDS, £10,000,000.

ARRANGEMENTS AS TO SURRENDER, NON-FORFEITURE, LOANS ON POLICIES, IMMEDIATE PAYMENT OF CLAIMS, DEFERRED RESIDUES, &c. are specially liberal

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys

The Photo Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduc-
tion of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs

The Instrument is fitted with
an Aluminium Body, 6 in
Armature Circle, revolving with
Vernier to one minute of arc,
4 in Compass, divided to half
degrees. Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £46.

Descriptive Pamphlets and Illustrated Description
of the Instrument sent free on application

THE THORNTON-PICKARD MANUFACTURING CO. LTD., ALTRINCHAM

JAS. J. HICKS, 8, 9 & 10 HATTON GARDEN, LONDON.

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special
construction, and a simple and accurate arterial pressure gauge.
It is marvellously sensitive, and consists of a metal tambour,
the expansion of which is exhibited in a highly magnified form
by means of an index or pointer which travels round a dial.
This dial is graduated in millimetres of mercury. The armlet
pump and pressure gauge, when not in use, fit conveniently into
a leather case. By means of this instrument we believe that
the arterial pressure can be taken in man as rapidly, simply,
and accurately as the temperature can be taken with the clinical
thermometer.

Price £5. Spare Bag and Tube, 5s.

The Instrument has a 6-in. Dial, and is packed in a
neat Morocco Case with Handle.

UNIVERSITY OF LONDON, PRELIMINARY SCIENTIFIC AND INTERMEDIATE EXAMINATIONS IN BIOLOGY

LONDON HOSPITAL MEDICAL COLLEGE.

A Revision Class begins on Monday, June 20, at 10 a.m., and will be continued on Mondays and Tuesdays, 10-4, and on Wednesdays, 10-12.30, until the July Examination. Fees (including materials) to Students joining this Class, only £3.10. This Class is not confined to Students of the Hospital.

MUNRO SCOT 1, Warden

INSTRUCTION IN PURE CULTIVATION OF YEAST, According to HANSEN'S Methods

Courses for Beginners, as well as for Advanced Students in Physiology and Technology of Fermentation—Biological Analysis of Yeast. Manuals—E. Chr. Hansen, "Practical Studies in Fermentation" (London, 1900), Alfred Jørgensen, "Micro organisms and Fermentation" (London [F. W. Lyon], 1897). Further Particulars on Application to the Director, ALFRED JØRGENSEN, The Laboratory, Copenhagen V.

THE WELSH INTERMEDIATE EDUCATION ACT.

CARDIFF SCHEME.

The Governors are prepared to receive Applications for the Post of HEAD MASTER for the Cardiff Intermediate School for Boys. Intending Applicants may obtain particulars of the Appointment from the CLERK to the Governors, who will also supply copies of the Scheme. Applications, accompanied by not less than four recent Testimonials, and marked on cover, "Head Master," must be in the hands of the undersigned not later than Saturday, July 9 next.

By Order of the Governors

DAVID SHEPHERD, Clerk
1 Frederick Street, Cardiff, June 2, 1898

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.

ASSISTANT DEMONSTRATOR OF CHEMISTRY

This Post will be Vacant in July next. Applications and testimonials should be sent on or before June 18 next, to the undersigned, from whom particulars may be obtained.

THOMAS W. SHORE, M.D., Warden

UNIVERSITY OF ABERDEEN.

EXAMINERS FOR GRADUATION

The University Court will, at a Meeting in July, proceed to appoint, under Order No. 13, one person to be an Additional Examiner for Graduation in each of the following subjects, viz.—(1) Botany, (2) Chemistry, (3) Medical Jurisprudence and Public Health.

The Examiners will be appointed for a period of four years, from February 1, 1899, and each will receive a Grant of £30 per annum. None of the present holders of these Offices is eligible.

Applications, along with 15 Copies of Testimonials, should the Candidate think fit to submit any, are to be lodged with the SECRETARY, on or before July 5 ensuing.

ROBERT WALKER, M.A., Secretary

University of Aberdeen, June 14, 1898.

BOROUGH OF SWANSEA

MUNICIPAL TECHNICAL SCHOOL. LECTURER IN METALLURGY

Applications are invited for the above Post, which has been rendered vacant through the acceptance by Mr. ALBAN CHAMBERS, of an important works appointment. Salary, £200, rising by annual increments of £10 to £250. Copies of the Schedule of Duties may be obtained from the SECRETARY of the School. Applications, with one set of copies of testimonials, should be sent to the undersigned not later than Saturday, July 9.

G. S. TURPIN, M.A., D.Sc., Principal

COUNTY BOROUGH OF WEST HAM.

Applications are invited for the following Appointments on the Teaching Staff of the Municipal Technical Institute.

ASSISTANT LECTURER IN PHYSICS (£140 per annum)

DEMONSTRATOR IN PHYSICS and ENGINEERING (£100 per annum)

DEMONSTRATOR IN CHEMISTRY (£100 per annum)

Full particulars can be obtained by sending a fully addressed foolscap envelope to the Principal, Municipal Technical Institute, Romford Road, West Ham, E., before June 24, 1898.

By Order of the Council

FRED E. HILL, Esq., Town Clerk
Town Hall, West Ham, E., June 9, 1898

A STEWARD is Required for the Chemical Department of the WEST HAM MUNICIPAL TECHNICAL INSTITUTE. Wages to commence, 25s per week. Previous experience of similar work essential—Apply by letter to the Principal.

THE SALT SCHOOLS, SHIPLEY, YORKSHIRE.

SCIENCE MASTER Wanted for Day, Evening, and P.T. Central Classes. Candidates must have had good experience in teaching Chemistry, Physics, and Natural Science, and Mathematics. Commencing Salary, £200 per annum.

Applications to be sent to the undersigned before June 30, stating age, Experience, Degree, or other qualification, and copies of Testimonials. Particulars as to duties, &c. on application to

WILLIAM FRY, Organising Secretary

CITY OF BIRMINGHAM MUNICIPAL TECHNICAL SCHOOL.

The Corporation of Birmingham require the services, in September next, of an ASSISTANT TEACHER in CHEMISTRY and PHYSICS.

Salary to commence with, £200 per annum. £20 allowed as passage money. Full particulars and form of application will be forwarded on receipt of a stamped addressed foolscap envelope. The last date for sending in applications is June 27.

GEO. MEKILOR, Secretary
Office of the School, Suffolk Street,
June 6, 1898

SOUTH AFRICAN COLLEGE, CAPE TOWN.

ASSISTANT Wanted immediately to teach Engineering Drawing, Elementary Physics, Elementary Wood and Iron Work. Salary to commence with, £200 per annum. £20 allowed as passage money.

Applications, accompanied by certificates as to age and health, to be addressed "Care of the Publishers of NATURE, St. Martin's Street, W.C., and to reach them not later than June 24.

GORDON'S COLLEGE, ABERDEEN.

Wanted, a TEACHER of CHEMISTRY (for Day and Evening Classes), Salary, £50. Duties commence end of August. Applications to be lodged on or before 21st inst with the HEADMASTER, from whom particulars as to duties may be had.

ASTRONOMER will Loan his Fine 8-inch

Aperture Equatorial Telescope, by GALE (recent date). Clock work motion and all necessary adjuncts for Measurement, Spectroscopy, &c. Elevated position in famous health resort, two hours west of London.—"N", 47 Victoria Street, S.W.

Part I. Containing Papers read at the Scientific Meetings held in January and February 1898. With Eighteen Plates. Price to Fellows, 9s. 10s. to the Public, 12s.

TRANSACTIONS, Vol. XIV. Part 6, containing a Paper "On the Mammals obtained by Mr. John Whitehead with his recent expedition to the Philippines" by Oldfield Thomas

With Field Notes by the Collector. With Seven Plates. Price to Fellows, 9s. 10s. to the Public, 12s.

To be obtained at the Society's Office (11 Hanover Square, W.), or through any Bookseller.

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.

The Photo Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduction
of the photographs,
including the Magnetic
bearings,—thus considerably
reducing the time spent and the risk
of error in the interpretation of
the photographs.

The Instrument is fitted with
an Aluminium Body, 6-in.
Azimuthal Circle, reading with
Vernier to one minute of arc,
4-in. Compass, divided to half
degrees. Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description
of the Instrument sent free on application.

For prices and more detailed lists apply to Biological Laboratory, Plymouth

THE DIRECTOR

EPPE'S COCOAINE.

COCOA-NIB EXTRACT

The choicest roasted nibs (broken up beans) of the natural Cocoa on being subjected to powerful hydraulic pressure, give forth their excess of oil, leaving for use a finely flavoured powder — "Cocaine," a product which, when prepared with boiling water, has the consistence of tea, of which it is now, with many beneficially taking the place. Its active principle being a gentle nerve stimulant, supplies the needed energy without unduly exciting the system. Sold only in labelled Tins. If unable to obtain it of your tradesman, a Tin will be sent post free for 9 stamps. — JAMES EPPE and Co., Ltd., Homeopathic Chemists, London

PERKEN, SON & RAYMENT, 99 HATTON GARDEN, HOLBORN CIRCUS, LONDON.

LARGE MODEL ILLUSTRATING HERTZIAN WAVE MOTION.

As designed by Prof. SILVANUS P. THOMPSON.

Beautifully illustrating the propagation of the Wave, the progress of which may be watched, from the Oscillator until it reaches the Resonator and causes a responsive vibration.

THE NEW STIGMATIC LENS.

SERIES II 2/8

BRITISH DESIGN AND WORKMANSHIP.

Is the best All-round Lens for either Professional or Amateur use

Each lens will give perfect definition with full aperture to the extreme corners of the plate it is sold to cover with smaller stops it will cover at least two sizes larger, giving perfect sharpness all over the plate; and thus becoming a wide angle lens of the highest excellence. Either combination may be used separately, giving foci of about 1/2 and 2 times the length of that of the lens when used intact. The advantage of this being able to choose the best point of view, irrespective of distance, will be at once apparent to the artistic worker.

EQUIVALENT TO FOUR LENSES AT THE PRICE OF ONE

Eleven Sizes are now ready from 1/4 to 1 1/2 inches eq. focus.

MACMILLAN & CO.'S NEW BOOKS.

THE ROMANES LECTURE, 1898.

BY SIR ARCHIBALD GEIKIE, D.C.L., &c.

TYPES OF SCENERY AND THEIR INFLUENCE ON LITERATURE.

By Sir ARCHIBALD GEIKIE, D.C.L., F.R.S. Delivered in the Sheldonian Theatre June 1, 1898. Med 8vo, sewed, 2s net

LECTURES ON THE GEOMETRY OF POSITION. By PROF THEODOR

RFVF Translated from the Third German Edition by Prof THOMAS F HOLGATE, M.A., Ph.D. Part I. Medium 8vo, 10s net

VOLUME V NOW READY

A SYSTEM OF MEDICINE. By many Writers. Edited by THOMAS CLIFFORD

ALLBUTT, M.A., M.D., LL.D., F.R.C.P., &c. Volume V DISEASES OF THE RESPIRATORY SYSTEM; DISEASES OF THE CIRCULATORY SYSTEM. Demy 8vo, 25s net

A TEXT-BOOK OF ENTOMOLOGY, including the Anatomy, Physiology,

Embryology and Metamorphoses of Insects for use in Agricultural and Technical Schools and Colleges, as well as by the working Entomologist. By ALPHIUS S PACKARD, M.D., Ph.D., Professor of Zoology and Geology, Brown University. Demy 8vo, 18s net

SCOTSMAN—"The anatomy, embryology, and metamorphoses of insects are treated with as much detail as will be required by the specialist outside of his own province, while the treatment is such as will keep the philosophical bearings of each fact before the reader. A remarkable feature of the work is the fulness of its references."

VOLUME II NOW READY.

ELECTRO-PHYSIOLOGY. By W. BIEDEKMANN, Professor of Physiology in

Jena. Translated by FRANCES A. WELBY. With One Hundred and Forty-nine Figures. Vol II 8vo, 17s net. (Vol I. With One Hundred and Thirty-six Illustrations. 8vo, 17s net.)

ATHENÆUM—"The concluding volume of Miss Welby's translation of Prof Biedermann's 'Electro-Physiology' is both valuable and interesting. . . There is an excellent index. The translation is excellent, and Miss Welby is to be congratulated on the completion of her task."

A TEXT-BOOK OF BOTANY. By Dr. E. STRASBURGER, Dr. FRITZ NOLL, Dr.

H. SCHENCK, Dr. A. F. W. SCHIMPER. Translated from the German by H. C. PORTER, Ph.D., Assistant Instructor of Botany, University of Pennsylvania. With 594 Illustrations, in part Coloured. Medium 8vo, 18s net.

CAMBRIDGE REVIEW—"Should be welcomed by students. The whole subject is treated in a thoroughly scientific manner."

A TEXT-BOOK OF ZOOLOGY. By T. JEFFERY PARKER, D.Sc., F.R.S., Professor

of Biology in the University of Otago, Dunedin, N.Z., and WILLIAM A. HASWELL, M.A., D.Sc., F.R.S., Professor of Biology in the University of Sydney, N.S.W. In Two Vols. With Illustrations. Medium 8vo, 36s net.

SCIENCE PROGRESS—"The appearance of this important work, for which many of us have been eagerly waiting, will be hailed with pleasure. . . When we consider the difficulties under which these authors laboured, one in New Zealand the other in Sydney, the printers, publishers and artists in England, one can only marvel at the splendid work they have produced, one that will be useful both to the elementary and advanced student as well as to the teacher."

BRITISH MEDICAL JOURNAL—"The classification of the vertebrata strikes us as particularly good, and in advance of that used in any general text-book published up to the present time. . . We are specially glad to have the privilege of welcoming a sound and scientific zoological treatise not made in Germany."

NATURAL SCIENCE—"Further and Haswell" has been looked forward to with expectation for some time. We welcome it gladly now that it appears. It should be in the hands of all students, and even teachers will find it of value. . . It is so well illustrated, so clearly printed and generally good, that it will be found a useful addition to the student's and teacher's shelves."

A TREATISE ON MAGNETISM AND ELECTRICITY. By ANDREW GRAY,

LL.D., F.R.S., Professor of Physics in the University College of North Wales. In Two Volumes. Vol I, Demy 8vo, 14s net.

ELECTRICAL REVIEW—"The production of this work is creditable to the author, and to the distinguished school of physicists that trained him. The book is beautifully printed and got up, and will, no doubt, find a place on the shelves of all mathematical physicists."

AN ELEMENTARY COURSE OF PHYSICS. Edited by Rev. J. C. P. ALDOUS,

M.A., Chief Instructor H.M.S. *Britannia*, late Fellow of Jesus College, Cambridge. Demy 8vo, 7s 6d. In Three Parts. Part I MECHANICS, PROPERTIES OF MATTER; HYDROSTATICS; HEAT. By the EDITOR. 4s 6d.

Part II WAVE MOTION; SOUND; LIGHT. By W. D. EGGAR, M.A., Assistant-Master, Eton College. 2s 6d.

Part III MAGNETISM; ELECTRICITY. By F. K. BAKKELI, M.A., B.Sc., &c. 2s 6d. (*Britannia Series*)

NATURE—"The treatment of the various subjects is most lucid and thorough, and is evidently based on an intimate acquaintance with the requirements of students. Great pains have been taken to avoid looseness of statement, and the fact that some of the sections have had the advantage of the criticisms and suggestions of Lord Kelvin, Lord Rayleigh, and others, makes it a trustworthy book of reference. . . We believe it is destined to take a high place in our schools and colleges."

PRIMER OF PSYCHOLOGY. By EDWARD BRADFORD TITCHENER. Crown 8vo,

4s 6d. *CAMBRIDGE REVIEW*—"This book, of its kind, is good. . . the name of its author should almost be enough to guarantee this. . . Should prove adequate to that class of readers for whom it is designed."

THE DAVY FARADAY RESEARCH LABORATORY OF THE ROYAL INSTITUTION.

DIRECTORS.

The Right Hon. LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.S.

Professor DEWAR, M.A., LL.D., F.R.S.

SUPERINTENDENT OF THE LABORATORY
Dr. ALEXANDER SCOTT, M.A., D.Sc.

This Laboratory, founded by Dr. Ludwig Mond, F.R.S., as a Memorial of Davy and Faraday for the purpose of promoting original research in Pure and Physical Chemistry, will be open during the following Terms —

Michaelmas Term — Monday, October 3, to Saturday, December 17
Levi Term — Monday, January 9, to Saturday, March 25
Easter Term — Monday, April 17, to Saturday, July 27

Under the Deed of Trust, workers in the Laboratory are entitled, free of charge, to Gas, Electricity and Water, as far as available, and, at the discretion of the Directors, to the use of the apparatus belonging to the Laboratory, together with such materials and chemicals as may be authorised.

All persons desiring to be admitted as workers, must send evidence of scientific training, qualification, and previous experience in original research along with a statement of the nature of the investigation they propose to undertake.

Candidates must apply for admission during the course of the preceding Term.

Forms of Application can be had from the ASSISTANT SECRETARY, Royal Institution, Albemarle Street, W.

LINNEAN SOCIETY OF LONDON.

NOTICE IS HEREBY GIVEN, that a SPECIAL GENERAL MEETING of this Society will be held at Burlington House on Thursday, June 30, at 8 P.M., to elect a Councillor in the place of the late Mr. OSBERT SALVY, deceased, and for other business.

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument invented for Survey Work in Mountainous Districts, and for Military or Rapid Surveys.

The Photo-Theodolite automatically records on the photograph all, or nearly all, the data necessary for the reduction of the photographs, including the Magnetic bearings,—thus considerably reducing the risk of error in the interpretation of the photographs.

The Instrument is fitted with an Aluminium Body, 6-in. Azimuthal Circle, reading with Vernier to one minute of arc, 4-in. Compass, divided to half degrees. Telescope with erect and inverting Eyepieces, rapid Rectilinear Lens with Iris Diaphragm and Colour Screen, six double dark Slides in Mahogany Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description of the Instrument sent free on application.

THE SCIENTIFIC MAN'S, NATURALIST'S & TRAVELLER'S CAMERA

IS THE Stereoscopic Company's BINOCULAR,

Because when ready to take 12 Pictures it weighs 19 ounces only.

It is used like a Field Glass. Taken instantaneous and time exposures Gives Pictures 7 in by 5 in. when used with the simple printing and enlarging apparatus Price £5 5s. only Complete with enlarging apparatus, £10 10s. FREE Lessons to Purchasers.

From R. BOWDLER SHARPE, Esq., LL.D., Assistant Keeper, Zoological Department, British Museum.

"I have received the remainder of the proofs of my photographs, and I must say that I am delighted with them. I consider it one of the best day's work I ever did when I bought one of your 'Binocular' Cameras. The ease with which it is worked, and the excellent results obtained, make it a most pleasurable accompaniment of a summer's outing, and, in my case, go per cent of my Norway photographs, have come out beautifully, while even the small remainder cannot be considered failures. I think this is a grand result, when you remember that I had little or no experience of photography, and had only time for an hour's instruction in your room the day before I sailed, and, further, that I had to make my own dark room in Norway in the best way I could. I am looking forward to having much pleasure this summer from the future 'Binocular,' and I have recommended it to all my friends."

THE STEREOSCOPIC COMPANY,
106 and 108 REGENT STREET, W., and 84 CHEAPSIDE, E.C.

JAS. J. HICKS,

8, 9 & 10 HATTON GARDEN, LONDON.

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special construction, and a simple and accurate arterial pressure gauge. It is marvellously sensitive, and consists of a metal tambour, the expansion of which is exhibited in a highly magnified form by means of an index or pointer which travels round a dial. This dial is graduated in millimetres of mercury. The armlet pump and pressure gauge, when not in use, fit conveniently into a leather case. By means of this instrument we believe that the arterial pressure can be taken in man as rapidly, simply, and accurately as the temperature can be taken with the clinical thermometer

Price £5. Spare Bag and Tube, 5s.

The Instrument has a 5-in. Dial, and is packed in a real Morocco Case with Stand.

SCHOOL OF AGRICULTURE, GHEEZEH, near CAIRO.

The Egyptian Ministry of Public Instruction requires the services, in October, of a SENIOR and of a JUNIOR PROFESSOR of AGRICULTURE, for the School of Agriculture, Gheezeh.

The branches to be taught are Practical and Theoretical Agriculture, Agricultural Chemistry, Natural Science, and Book-keeping. Salaries: Senior post from about £450 per annum (£45 15 per mensem) to about £555 per annum (£45 15 per mensem); Junior post, from about £495 per annum (£45 15 per mensem). Allowance for Passage out to Egypt.

Applications, accompanied by copies only of testimonials, must be sent before August 15, to the Principal of the School, W. C. MACKENZIE, D.Sc., 6 Harrington Gardens, Edinburgh, to whom Candidates may apply, by letter, for further information.

THE WELSH INTERMEDIATE EDUCATION ACT. CARDIFF SCHEME.

The Governors are prepared to receive Applications for the Post of HEAD MASTER for the Cardiff Intermediate School for Boys. Intending Applicants may obtain particulars of the Appointment from the CLERK to the Governors, who will also supply copies of the Scheme. Applications, accompanied by not less than four recent Testimonials, and marked on cover, "Head Master" must be in the hands of the undersigned not later than Saturday, July 9 next.

By Order of the Governors
DAVID SHEPHERD, Clerk

1 Frederick Street, Cardiff, June 7, 1898

UNIVERSITY OF GLASGOW.

The University Court of the University of Glasgow will shortly proceed to appoint a LECTURER on MATERIA MEDICA and THERAPEUTICS, to conduct the Classes for WOMEN STUDENTS in that subject at QUEEN MARGARET COLLEGE. The Salary attached to the Lectureship is £150 per annum (being £100 for Winter Session and £50 for Summer Session), and the appointment will date from October 1 next. Candidates should lodge Twenty Copies of their Application and Testimonials with the undersigned, on or before July 30, 1898.

ALAN E. CLAPPERTON, Secretary of the Court.
91 West Regent Street, Glasgow

UNIVERSITY COLLEGE OF SHEFFIELD.

The Post of ASSISTANT LECTURER and DEMONSTRATOR of PHYSICS is Vacant. Salary, £150 per annum. Particulars on application to the Principal.

THE DURHAM COLLEGE OF SCIENCE, NEWCASTLE-UPON-TYNE. DEMONSTRATOR IN ENGINEERING

The Council invite applications for the above Post. Applicants must have a Workshop Experience and sound theoretical knowledge of Mechanics, and be capable of preparing for and carrying out, under the Professor of Engineering, the various Demonstrations of a Laboratory, including Experimental Engine and Boiler Tests. Salary, £150 per Annum, rising by annual increments of £10 to £160 per Annum. Duties will commence on September 1 next. Applications and Testimonials must be sent to the SECRETARY not later than July 31, 1898.

EAST LONDON TECHNICAL COLLEGE, PEOPLE'S PALACE, E.

The Governors propose shortly to appoint a LECTURER in ELECTRICAL ENGINEERING, whose services will be required on Four Evenings in the Week, for about Forty Weeks in the Year. Salary, £120 per Annum.

Applications, with Three (Copy) Testimonials, must be sent to the TREASURER before July 9. Further particulars on application to the DIRECTOR OF STUDIES.

OWENS COLLEGE, MANCHESTER.

The Senate are prepared to appoint a SENIOR and a JUNIOR DEMONSTRATOR IN PHYSIOLOGY.

The stipends will be £150, rising to £200, and £100, rising to £150, respectively.

Applications should be made, on or before July 18, to the REGISTRAR, from whom further particulars may be obtained.

SYDNEY CHAFFERS, Registrar

INTERMEDIATE SCHOOL, PORT TALBOT, S. WALES.

Required, in September, a SCIENCE GRADUATE, chiefly for Chemistry and Physics. One able to assist in Elementary, French, and General Form subjects preferred. Must be experienced, and a good disciplinarian. Salary £150, non resident, which might be increased by Evening Classes under the Science and Art Department. Apply, not later than July 11, to the HEADMASTER.

PHYSICAL DEMONSTRATOR (Camb. and Russ), aged Twenty-two, desires Re-engagement. Experience in Coll. of Sci.—Address, "O. N.," NATURE OFFICE.

EXPERIMENTAL PSYCHOLOGY.

UNIVERSITY COLLEGE, LONDON.

Mr E. T. DIXON, M.A., will conduct Practical Course next Term. If possible, a Special Course will be arranged for Teachers. For Prospectus apply to

J. M. HORSBURGH, M.A., Secretary

INSTRUCTION IN PURE CULTIVATION OF YEAST,

According to HANSEN'S Methods

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys

The Photo Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduction
of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs

The instrument is fitted with
an Aluminum Body, 6-in.
Azimuthal Circle, reading with
Vernier to one minute of arc,
4-in. Compass, divided to half
degrees Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £45.

REISSUE OF STANFORD'S COMPENDIUM OF GEOGRAPHY & TRAVEL.

ENLARGED, AND IN GREAT PART REWRITTEN

In 12 Volumes, with New Illustrations and Maps, 12s each

"The new issue of 'Stanford's Compendium of Geography and Travel' is a publication of great value, and contains, in convenient form, the latest geographical results of travel and research adequately treated. Not only is the information accurate, but the form in which the work is produced is admirable, and English geography may be proud of such a series. It is useful for educational purposes and for reference, and pleasant to the general reader."—*Athenaeum*

Just Published, large crown 8vo, cloth, 12s

NORTH AMERICA.

VOL. II

THE UNITED STATES.

By HENRY GANNETT,

Chief Geographer of the United States (Geological Survey)

With 16 Maps and 72 Illustrations

The Volumes already issued of the New Series include—
NORTH AMERICA.—Vol. I. CANADA
and **NEWFOUNDLAND** By SAMUEL EDWARD DAWSON,
F.R.S. (Lond.) F.R.C. With 18 Maps and 90 Illustrations

"The general scope and execution of the work, like those of its predecessors, are admirable."—*Athenaeum*

"The author has done his work thoroughly, giving a fuller and more satisfactory account of the Dominion than has previously been published."—*Geographical Journal*

AUSTRALASIA.—Vol. I. AUSTRALIA
and **NEW ZEALAND** By ALFRED RUSSEL WALLACE,
LL.D., D.C.L., F.R.S. With numerous Maps and Illustrations

"To the general reader, and especially to the subdivision of that extensive genus included in the term 'interesting visitors' to Australia, Dr Wallace's book may be confidently recommended."—*Saturday Review*

AUSTRALASIA.—Vol. II. MALAYSIA
and the **PACIFIC ARCHIPELAGOS** By T. H. GUILLE
MARD, M.D., Author of "The Cruise of the *Marchena*" With
numerous Maps and Illustrations

"Dr Guillemand's volume is certainly the most interesting and accurate account extant on the tropical portion of the Eastern Archipelago."—*Nature*

AFRICA.—Vol. I. NORTH AFRICA. By
A. H. KEANE, F.R.G.S., Author of "Asia" in same Series,
"Eastern Geography," &c. With 9 Maps and 77 Illustrations

"The preparation of the book must have involved immense and original labour, for the volume in the former series by the late Keith Johnston has been entirely superseded. Mr. Keane is to be complimented on the manner in which he has discharged his task."—*Glasgow Herald*

AFRICA.—Vol. II. SOUTH AFRICA. By
A. H. KEANE, F.R.G.S., Author of "North Africa" in same Series,
"Eastern Geography," &c. With 11 Maps and 92 Illustrations

"An admirable repository, not merely of geographical information proper, but of so much of history, ethnography, and political vicissitudes as is required to illustrate and explain the geography."—*Times*

**ASIA.—Vol. I. NORTHERN and
EASTERN ASIA, CAUCASIA, RUSSIAN TURKSTAN,
SIBERIA, CHINESE EMPIRE, and JAPAN** By A. H.
KEANE, F.R.G.S. With 8 Maps and 91 Illustrations

"Mr. Keane, with practised skill, has brought together a wide and most impressive array of facts and statistics, and has book his additional advantage of numerous illustrations, a copious index, and a singularly fine set of coloured maps."—*Spencer*

**ASIA.—Vol. II. SOUTHERN and
WESTERN ASIA, AFGHANISTAN, INDIA, INDO-CHINA,
MALAY PENINSULA, TURKEY in ASIA, ARABIA, and
PERSIA.** By A. H. KEANE, F.R.G.S. With 7 Maps and 89
Illustrations

"Like the first volume, it has been almost entirely recast and to a large extent rewritten. The two volumes form a most useful summary of the geography of what is in some respects the most interesting of all the continents."—*Times*

"EUROPE" and "CENTRAL and SOUTH
AMERICA" are in active preparation.

EPPS'S COCOAINE.

COCOA-NIB EXTRACT.

The choicest roasted nibs (broken up beans) of the natural Cocoa on being subjected to powerful hydraulic pressure, give forth their excess of oil, leaving for use a finely-flavoured powder—"Cocoaine," a product which, when prepared with boiling water, has the consistence of tea, of which it is now, with many beneficially taking the place. Its active principle being a gentle nerve stimulant, supplies the needed energy without unduly exciting the system. Sold only in labelled Tins. If unable to obtain it of your tradesman, a Tin will be sent post free for 9 stamps.—JAMES EPPS & CO., LTD., Homoeopathic Chemists, London.

THE NEW STIGMATIC LENS.

SERIES II. F/6.

BRITISH DESIGN AND WORKMANSHIP.

is the best All-round Lens for either Professional or Amateur use.

Each lens will give perfect definition with *full aperture* to the extreme corners of the plate it is sold to cover, with smaller stops it will cover at least two sizes larger, giving perfect sharpness all over the plate, and thus becoming a wide angle lens of the highest excellence. Either combination may be used separately, giving foci of about $1\frac{1}{2}$ and 2 times the length of that of the lens when used intact. The advantage of this being able to choose the best point of view, irrespective of distance, will be at once apparent to the artistic worker.

EQUIVALENT TO FOUR LENSES AT THE PRICE OF ONE.

Eleven Sizes are now ready from $3\frac{1}{2}$ to 18 inches eq. focus.

THE DAVY FARADAY RESEARCH LABORATORY OF THE ROYAL INSTITUTION.

DIRECTORS

The Right Hon. LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.S.

Professor DEWAR, M.A., LL.D., F.R.S.

SUPERINTENDENT OF THE LABORATORY

DR ALEXANDER SCOTT, M.A., D.Sc.

This Laboratory, founded by Dr. Ludwig Mond, F.R.S., as a Memorial of Davy and Faraday for the purpose of promoting original research in Pure and Physical Chemistry, will be open during the following Terms—
Michaelmas Term—Monday, October 3, to Saturday, December 17
Levi Term—Monday, January 9, to Saturday, March 25
Easter Term—Monday, April 17, to Saturday, July 9.

Under the Deed of Trust, workers in the Laboratory are entitled, free of charge, to Gas, Electricity and Water, as far as available, and, at the discretion of the Directors, to the use of the apparatus belonging to the Laboratory, together with such materials and chemicals as may be authorized.

All persons desiring to be admitted as workers, must send evidence of scientific training, qualification, and previous experience in original research along with a statement of the nature of the investigation they propose to undertake.

Candidates must apply for admission during the course of the preceding Term.

Forms of Application can be had from the ASSISTANT SECRETARY, Royal Institution, Albemarle Street, W.

BATTERSEA POLYTECHNIC, S.W.

The Governing Body require the services of an ASSISTANT LECTURER and DEMONSTRATOR in the Department of Physics and Electrical Engineering. For particulars send stamped addressed envelope at once to the SECRETARY.

UNIVERSITY COLLEGE OF NORTH WALES (BANGOR).

SESSION 1898-99 will open on TUESDAY, OCTOBER 4.

DEPARTMENTS OF PHYSICS, CHEMISTRY, AND BIOLOGY

PHYSICS — Prof. A. GRAY, M.A., LL.D., F.R.S.
Assistant Lecturers and Demonstrators, T. C. BAILLIE, M.A., B.Sc., and E. TAYLOR JONES, D.Sc.
Prof. J. J. DOUGLAS, M.A., D.Sc.
CHEMISTRY — Assistant Lecturer and Demonstrator, F. MARSDEN, M.Sc., Ph.D. (Heidelberg).
Botany—Prof. R. W. PHILLIPS, M.A., B.Sc.
BIOLOGY — Assistant Lecturer and Demonstrator, J. LLOYD WILLIAMS.
Zoology—Prof. PHILIP J. WHITE, M.B., F.R.S.E.

The Classes and Laboratory Courses of this College are arranged to suit the requirements of Students of Practical Science, as well as of Students preparing for University and other Examinations. The Lectures in Chemistry, Physics, Botany, and Zoology, are recognised by the Universities of Edinburgh and Glasgow as qualifying for the Medical Degrees of those Universities. One *Annus Medicus* may be taken at this College.

The extensive Laboratories (Physical, Chemical, and Biological) are fully equipped for Study and Research, and in the Physical Department special provision has been made for the Teaching of Electrical Engineering. A Special Course has been arranged in this subject.

Inclusive Tuition Fee, £14 14

LABORATORY FEES (per Term)

on the scale of £12 for six hours a week, in each Department.

A considerable number of Scholarships and Exhibitions are open for competition at the beginning of each Session, and several are awarded at the close of each Session on the result of the year's work.

For full information as to Science and Arts Courses, apply for Prospectus to the Secretary and Registrar, J. E. LLOYD, M.A.

BALLIOL COLLEGE, CHRIST CHURCH, AND TRINITY COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIPS AND EXHIBITIONS

A Combined Examination for Natural Science Scholarships and Exhibitions will be held by the above Colleges, beginning on TUESDAY, NOVEMBER 15, 1898.

Three Scholarships and Two Exhibitions will be offered, the Scholarships being worth £80 a year.

The Subjects for Examination will be Physics, Chemistry, and Biology, but Candidates will not be expected to offer themselves in more than two of these.

Particulars may be obtained by application to
Christ Church, Oxford, A. VERNON HARCOURT.

EDINBURGH SCHOOL OF MODERN LANGUAGES, 1898.

A SUMMER MEETING will be held at Outlook Tower, University Hall, from August 1 to 27. Lectures on French and English Languages and Literature, Social Science, Geography, History, &c.
Full particulars on application to the Secretary, T. R. MARK.

UNIVERSITY OF ST. ANDREWS.

CHAIRS OF MATERIA MEDICA AND PATHOLOGY

In accordance with the terms of Ordinance No. 47, St. Andrews No. 6, of the Commissioners under the Universities (Scotland) Act, 1856, the University Court will appoint PROFESSORS OF MATERIA MEDICA and PATHOLOGY, who shall conduct Classes at Dundee qualifying for graduation in Medicine, the Appointments to date from October 1, 1898.

Applications, accompanied by thirty copies of testimonials, to be lodged, by August 31 next, with Mr. STUART GRACE, Secretary of the University Court, from whom further information may be obtained.
St. Andrews, June 1898.

ROYAL AGRICULTURAL COLLEGE, CIRENCESTER.

IN COLLEGE RESIDENT PROFESSORSHIP OF MATHEMATICS
AND PHYSICS

Applications are invited by the Governing Body for the above, to be sent in (with statement of age, qualifications, testimonials) to the PRINCIPAL, on or before Saturday, July 23. Salary about £185 per annum, with Board and Rooms in College. Particulars on application.

TECHNICAL COLLEGE, HUDDERSFIELD.

The following Vacancies occur: DEMONSTRATOR OF PHYSICS, £100 per annum; ASSISTANT LECTURER in ENGLISH and LATIN, £75 per annum.

Applications to be sent in to the PRINCIPAL, not later than July 11. Statement of duties and further particulars may be obtained on application.

THOS. THORP, Secretary

GUY'S HOSPITAL MEDICAL SCHOOL.

Applications are invited for the post of LECTURER in BIOLOGY, and should be addressed to the TREASURER, Guy's Hospital, S.E., on or before Saturday, July 23, 1898.

ELECTRICAL ENGINEERING.

THE ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTION, 8 CHARKING CROSS ROAD, LONDON
(Proprietors—Syndicate of Electrical Engineers, Ltd.)

BOARDS OF GOVERNORS.
The Rt. Hon. the Earl of CRAWFORD, K.T., F.R.S., Chairman
The Rt. Hon. Lord Castletown
The Hon. R. Brougham
Robert Hammond
Hugh Esra Harrison
Francis Ince
William O. Smith

Affords a Theoretical and Practical Training, and qualifies the Sons of Gentlemen for Appointments in Mechanical and Electrical Engineering After the Preliminary Training in Theory at the Institution. Students go through a Practical Course, first in the Mechanical Engineering Works, and subsequently the Electrical Works, the Institution being associated with over 50 leading Firms and Engineers for this purpose. They are thus brought directly into association with prominent Companies and Firms, and secure an introduction to the Profession under the most favourable auspices. **APPOINTMENTS HAVE BEEN SECURED FOR OVER 80 PER CENT OF THE STUDENTS** who have completed their Course since the foundation of the Institution, and applications continue to be received for competent men. Prospectus on application.

**THE ELECTRICAL
AND
GENERAL ENGINEERING COLLEGE,
AND
EXPERIMENTAL ENGINEERING
WORKS,**

**2 and 4 PENYVERN ROAD, EARL'S COURT,
LONDON, S.W.,**

Trains Students for Electrical, Mechanical and Mining Engineering
Develops Electrical and Mechanical Patents
Constructs Experimental and Special Machinery and Models to Specification

**INSTRUCTION IN
PURE CULTIVATION OF YEAST,**

According to **HANSEN'S Methods**

Courses for Beginners, as well as for Advanced Students, in Physiology and Technology of Fermentations—Biological Analysis of Yeast
Manuals—E. Chr. Hansen "Practical Studies in Fermentation"
London (Spain), 1896. Alfred Jørgensen "Micro-organisms and Fermentation" London (F. W. Lyon), 1893

Further Particulars on Application to the Director, **ALFRED JØRGENSEN**, The Laboratory, Copenhagen, V.

SCIENCE TUITION.

PREPARATION BY CORRESPONDENCE AND ORAL TUITION for all Science Examinations—Matriculation, B.Sc., Prel. Sci., &c.
SINGLE SUBJECTS TAKEN—Chemistry, Physics, Botany, Zoology, &c.
SPECIAL CLASSES in Botany and Chemistry
TUTORIALS—The Staff includes Graduates of London, Oxford, Cambridge, and Royal Universities

NO TEMPERATURE ERROR.

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys

The Photo-Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduction
of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs

The Instrument is fitted with
an Aluminium Body, 6-in
Azimuthal Circle, reading with
Verner to one minute of arc,
4-in. Compass, divided to half
degrees. Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description
of the Instrument sent free on application

CARD AND SLIP FILES.

Portion of Card File

The Ceres Card Files in Cabinets (with rod) for Library
Catalogues, and in Boxes and Trays (without the rod) for other
purposes, constitute the latest development of the Card System

The Bishop of Bristol:—"The convenience of the Writing
Table with 'Ceres' Files is beyond words. So far as I can keep
pace with my correspondence, there is never anxiety as to where
a letter is; and the drawer with cards for notes of references,
speeches, sermons, &c., makes me perpetually regret that I had
not such a thing twenty years ago."

Sir H. H. Bemrose, M.P.:—"I am using the Card Box
daily for a literary purpose, and I find it simply invaluable. As
it lies on the table entries are made at the moment under their
proper heads, and the facility of reference is such as no other mode
of indexing I am aware of can touch."

NEWMAN & GUARDIA, Ltd.,
90 & 92 Shaftesbury Avenue, London, W

JAS. J. HICKS, 8, 9 & 10 HATTON GARDEN, LONDON,

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special
construction, and a simple and accurate arterial pressure gauge.
It is marvellously sensitive, and consists of a metal tambour,
the expansion of which is exhibited in a highly magnified form
by means of an index or pointer which travels round a dial.
This dial is graduated in millimetres of mercury. The armlet
pump and pressure gauge, when not in use, fit conveniently into
a leather case. By means of this instrument we believe that
the arterial pressure can be taken in man as rapidly, simply, and
accurately as the temperature can be taken with the clinical
thermometer.

Price £5. Spare Bag and Tube, 5s.

The Instrument has a 5-in. Dial, and is packed in a
neat morocco Case with Handle.

Provides Courses of Intermediate Instruction for Day Students not under 14 years of age, preparing to enter Engineering and Chemical Industries. Fees, £15 per Session. Professors:—

Physics and Electrical Engineering S. P. THOMPSON, D.Sc., F.R.S.
Mechanical Engineering and Mathematics W. E. DALY, M.A., B.Sc., M.I.M.E.
Chemistry R. MELDOLA, F.R.S., F.I.C.

JOHN WATNEY, Hon. Secretary

City and Guilds of London Institute,
Graham College, Basinghall Street, E.C.

UNIVERSITY COLLEGE OF NORTH WALES (BANGOR).

SESSION 1898-99 will open on TUESDAY, OCTOBER 4
DEPARTMENTS OF PHYSICS, CHEMISTRY, AND BIOLOGY

PHYSICS ... Prof. A. GRAY, M.A., LL.D., F.R.S.
Assistant Lecturers and Demonstrators, T. C. BAILEY, M.A., B.Sc., and Taylor Jones, D.Sc.
Prof. J. J. DODDIE, M.A., D.Sc.
CHEMISTRY ... Assistant Lecturer and Demonstrator, b. MARSDEN, M.Sc., Ph.D. (Hedberg).
Botany—Prof. R. W. PHILLIPS, M.A., B.Sc.
BIOLOGY ... Assistant Lecturer and Demonstrator, J. LLOYD WILLIAMS.
Zoology—Prof. PHILIP J. WHITE, M.B., F.R.S.E.

The Classes and Laboratory Courses of this College are arranged to suit the requirements of Students of Practical Science, as well as of Students preparing for University and other Examinations. The Lectures in Chemistry, Physics, Botany, and Zoology, are recognised by the Universities of Edinburgh and Glasgow as qualifying for the Medical Degrees of those Universities. One *Anatomia Medica* may be taken at this College.

The extensive Laboratories (Physical, Chemical, and Biological) are fully equipped for Study and Research, and in the Physical Department special provision has been made for the Teaching of Electrical Engineering. A special Course has been arranged in this subject.

Inclusive Tuition Fee, £41.

LABORATORY FEES (per Term)

on the scale of £1 1s. for six hours a week, in each Department.

A considerable number of Scholarships and Exhibitions are open for competition at the beginning of each Session, and several are awarded at the close of each Session on the result of the year's work.

For full information as to Science and Arts Courses, apply for Prospectus to the Secretary and Registrar, J. E. LLOYD, M.A.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

ELECTRICAL ENGINEERING

Professor ANDREW GRAY, M.D., F.R.S., will begin, in OCTOBER next, a Systematic COURSE OF INSTRUCTION in Electrical Machinery and Practical Electricity. The Physical Laboratory is fully equipped with a Compound Beam Engine, Dynamo, Transformer, Secondary Battery, and the most approved Measuring Instruments for all Branches of Electrical Engineering. Laboratory Fees at the rate of £1 1s. per Term for six hours per week. Composition Fee for all College Lectures for the Session, £10.

Applications for Calendar, Prospectus, and general information to be made to

J. E. LLOYD, M.A., Secretary and Registrar

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

ASSISTANT LECTURER AND DEMONSTRATOR IN ANATOMY

The Council is prepared to appoint an ASSISTANT LECTURER and DEMONSTRATOR in ANATOMY, at a Salary of £150 per Annum. TEMPORARY ASSISTANT LECTURER and DEMONSTRATOR IN PHYSIOLOGY.

The Council is prepared to appoint, for One Year, an ASSISTANT LECTURER and DEMONSTRATOR in PHYSIOLOGY at a Salary of £150.

Applications for these Posts, together with Testimonials, which need not be printed, to be sent to the undersigned on or before July 30, 1898.

University College, Cardiff, July 7, 1898. J. AUSTIN JENKINS, B.A., Registrar

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, BURLINGTON HOUSE, LONDON, W.

THE NEXT ANNUAL MEETING OF THE ASSOCIATION will be held at BRISTOL, commencing on WEDNESDAY, SEPTEMBER 7, 1898.

PRESIDENT ELECT

Sir WILLIAM CROOKES, F.R.S., V.P.C.S.

Notice of Papers proposed to be read should be sent to the Office, Burlington House, before AUGUST 1.

Information about local arrangements may be obtained from the LOCAL SECRETARIES, Philosophic Club, Bristol.

G. GRIFITH, Assistant General Secretary.

UNIVERSITY OF ST. ANDREWS.

CHAIRS OF MATERIA MEDICA AND PATHOLOGY.

In accordance with the terms of Ordinance No. 47, St. Andrews No. 6, of the Commissioners under the Universities (Scotland) Act, 1859, the University Court will appoint PROFESSORS OF MATERIA MEDICA AND PATHOLOGY, who shall conduct Classes and receive qualifying for graduation in Medicine. The Appointments to date from October 1, 1898.

Applications, accompanied by thirty copies of testimonials, to be lodged, by August 31 next, with Mr. STUART CRACK Secretary of the University Court, from whom further information may be obtained. St. Andrews, June 1898.

CITY OF BIRMINGHAM MUNICIPAL TECHNICAL SCHOOL.

The Corporation require the services of a HEAD TEACHER of the Engineering and Workshop Classes of the School. Salary, £300 per annum.

Full particulars of the post and form of application will be forwarded on receipt of a stamped addressed folio post envelope.

GEO. MELLOR, Secretary
Offices of the School, Suffolk Street,
July 5, 1898.

CITY OF BIRMINGHAM MUNICIPAL TECHNICAL SCHOOL.

The Corporation require the services in September next of an ASSISTANT MASTER for the Day School. Salary, £125.

Full particulars and form of application will be forwarded on receipt of a stamped addressed folio post envelope. The last date for sending in applications is the 31st inst.

GEO. MELLOR, Secretary
Offices of the School, Suffolk Street,
July 5, 1898.

MCGILL UNIVERSITY, MONTREAL.

Applications are invited for the Post of ASSISTANT PROFESSOR OF CIVIL ENGINEERING.

Candidates should have had Experience in Teaching, and must possess a thorough knowledge of the Theory of Structures and of Hydraulics. They should also be prepared to undertake the superintendence of Designing.

Apply at once, by letter, to the PRINCIPAL, 11 Mifflin Road, Oxford.

BRUNT'S TECHNICAL SCHOOL, MANSFIELD.

A THIRD ASSISTANT MASTER Required, to commence in Sept. next. To take part in the work of the Schools of Science. Experience in Physical Laboratory highly desirable. Salary, £70 per annum. Apply, with copies of testimonials, to the HEADMASTER, C. E. STACKEY, B.A., B.Sc.

UNIVERSITY COLLEGE OF SHEFFIELD.

The Post of ASSISTANT LECTURER and DEMONSTRATOR OF PHYSICS is Vacant. Salary, £150 per annum. Applications to be made before July 23. Particulars on application to the REGISTRAR.

UNIVERSITY COLLEGE OF SHEFFIELD.

The Council propose to appoint an ASSISTANT LECTURER in MATHEMATICS. Salary £750. Applications to be made before July 23. Particulars from the REGISTRAR.

WORCESTERSHIRE COUNTY COUNCIL

ADDITIONAL COUNTY ANALYST

The Sanitary Committee of the Worcestershire County Council are prepared to receive applications from duly qualified persons for the Appointment of an Additional County Analyst for the Administrative County of Worcester (exclusive of the County Boroughs of Worcester and Dudley) under the Sale of Food and Drug Act 1875, and the Fertilisers and Feeding Stuffs Act 1893.

Salary, £400 per annum, payable monthly, together with all necessary out-of-pocket expenses, which may be received from persons between 25 and 40 years of age, and capable of carrying out bacteriological researches. A person qualified to lecture on chemistry as applied to agriculture will be preferred. The person appointed will, unless specially arranged to the contrary, have to devote the whole time to the service of the Council, and reside in or near Worcester. He must give security in such amount and of such nature as may from time to time be fixed and approved by the Finance Committee. He will be permitted, with the approval of the Sanitary Committee, to take a limited number of pupils, and must, if required, be prepared to lecture on and teach Analytical and Bacteriological Work. He will also be required to do such Analytical and Bacteriological Investigations as may be directed by the County Council.

The Appointment will be held subject to six months notice on either side, which may be given at any time. No superannuation or Pension will be paid. Office and Laboratory will be provided by the Council, together with all necessary Books, Stationery, Instruments, Chemicals, and other appliances. He will not be allowed to undertake private Research Work, unless with the consent of the County Council.

The Appointment will be subject to the approval of the Local Government Board and also of the Board of Agriculture.

Applications, stating the candidate's age, where educated, present position, and previous experience, especially as to analytical and bacteriological work, must be made in the Applicant's own handwriting, on paper of foolscap size, accompanied by not more than six copies of recent testimonials, addressed to the undersigned and marked "County Analysts", so that it shall be received by 5 p.m. on Friday, the 19th day of August, 1898, and no application afterwards received will be entertained.

It is understood that the person appointed will also be appointed by the Corporation of Worcester to act as Analyst for the City of Worcester at an extra salary.

A printed statement of the duties may be obtained from me. Convancing in any form will be absolutely disqualifying.

Selected candidates will be required to attend a Meeting of the Sanitary Committee of the County Council, notice of which will be given.

The person appointed must be prepared to enter upon his duties not later than October 1, 1898, and pass a Medical Examination by an approved person.

S. THORNELLY, Clerk of the County Council
Shirhall, Worcester, July 14/98

THE WALSALL VICTORIA INSTITUTE.

The Technical Instruction Committee of the Walsall Victoria Institute require a DIRECTOR OF TECHNICAL INSTRUCTION, whose duties shall comprise the Organisation and Superintendence, under the Committee, of Classes in Science, Art, Literature, Music, and Technology; the secretarial Work, and the Management of the Accounts of the Institute. The Director will be required to devote his whole time to the service of the Institute and must have a knowledge of the routine and regulations of the Science and Art Department. Salary, £200 per Annum.

Further particulars obtained on application to the undersigned, on receipt of stamped addressed foolscap envelope.

Applications endorsed "Director of Technical Instruction, stating age, experience, qualifications, with three Testimonials, and recent Photograph, must be sent to the CHAIRMAN of the TECHNICAL INSTRUCTION COMMITTEE, Victoria Institute, Walsall, before Thursday, the 28th day of July next.

ALFRED BYCKETT, Secretary (pro tem).
Walsall Victoria Institute, July 14, 1898

SWINDON AND NORTH WILTS TECHNICAL SCHOOL.

The Committee require the Services of a SCIENCE MASTER for Day and Evening Classes.

The Master will be required to teach Practical Geometry and such other subjects as may be arranged.

Preference will be given to a Candidate with qualifications in Mathematics and Physics.

Salary, £150 per annum.

Particulars and Forms of Application, which should be returned not later than July 21, may be obtained from the SECRETARY, Swindon and North Wilt Technical School, Victoria Road, Swindon, Wilts.

TECHNICAL COLLEGE, HUDDERSFIELD

THE LECTURESHIP IN ENGINEERING is Vacant. Salary £250 per annum.

Applications to be sent in to the PRINCIPAL, not later than August 9. Statement of duties may be obtained upon application to

THOS. THORP, Secretary

TO BE SOLD, by PRIVATE CONTRACT,
the well-arranged and preserved Collection of LEPIDOPTERA (comprising many unique specimens), about a Thousand or more in number, made in the County of Lancashire and elsewhere by the late A. H. BUCHERAN. Apply, by letter first, to Mrs. BUCHERAN, 126 Burchenger Road, South Norwood.

Sale by Auction.

TUESDAY and WEDNESDAY, JULY 19 and 20
The Library of Works on Natural History and other subjects. Also the Shells, Corals, Minerals, together with several well made Rosewood and Maplewood Cabinets and Showcases, the property of the late Miss BANKS, to which is added the Birdskins and Eggs and Cases of Birds, &c., from the Collection of the late Mr. JOHN CALVERT. Also a Collection of Beautiful Australian Birdskins, the property of a Lady leaving England. British Lepidoptera and Books from the Collection of J. A. PAUL, Esq. Heads and Horns of Animals &c., &c.

MR. J. C. STEVENS will Sell the above by Auction at his Great Room, 28 King Street, Covent Garden, on TUESDAY and WEDNESDAY next, JULY 19 and 20, at half past 12 precisely.

On view Day prior, from 12 till 4, and Morning of Sale. Catalogues had.

EXPERIMENTAL AND SCIENTIFIC GLASS-BLOWING.

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.

The Photo Theodolite automatically records on the photograph all, or nearly all, of the data necessary for the reduction of the photographs, including the Magnetic bearing,—thus considerably reducing the time spent and the risk of error in the interpretation of the photographs.

The Instrument is fitted with an Aluminum Body, 6-in. Azimuthal Circle, reading with Vernier to one minute of arc, 4-in. Compass, divided to half degrees. Telescope with erect and inverting Eyepieces, rapid Rectilinear Lens with Iris Diaphragm and Colour Screen, six double dark Slides in Mahogany Case, with Sund compass, £45.

Descriptive Pamphlets and Illustrated Description
of the Instrument sent free on application.

THE NEW STIGMATIC LENS.

SERIES II F/8

BRITISH DESIGN AND WORKMANSHIP.

Is the best All-round Lens for either Professional or Amateur use

Each lens will give perfect definition with *full aperture* to the extreme corners of the plate it is sold to cover with smaller stops it will cover at least two sizes larger, giving perfect sharpness all over the plate, and thus becoming a wide angle lens of the highest excellence. Either combination may be used separately giving foci of about 18 and 2 times the length of that of the lens when used intact. The advantage of thus being able to choose the best point of view, irrespective of distance, will be at once apparent to the artistic worker.

EQUIVALENT TO FOUR LENSES AT THE PRICE OF ONE.

Eleven Sizes are now ready from $3\frac{1}{4}$ to 18 inches eq focus

THE DAVY FARADAY RESEARCH LABORATORY OF THE ROYAL INSTITUTE.

DIRECTORS

The Right Hon. LORD RAYLEIGH, M.A., D.C.L.,
LL.D., F.R.S.

Professor DEWAR, M.A., LL.D., F.R.S.

SUPERINTENDENT OF THE LABORATORY

DR. ALEXANDER SCOTT, M.A., D.Sc.

This Laboratory, founded by Dr. Ludwig Mond, F.R.S., as a Memorial of Davy and Faraday for the purpose of promoting original research in Pure and Physical Chemistry, will be open during the following Terms—

Michaelmas Term—Monday, October 3, to Saturday, December 17.
 Lent Term—Monday, January 9, to Saturday, March 25. *Easter Term*—Monday, April 17, to Saturday, July 29.

Under the Deed of Trust, workers in the Laboratory are entitled, free of charge, to Gas, Electricity and Water, as far as available, and, at the discretion of the Directors, to the use of the apparatus belonging to the Laboratory, together with such materials and chemicals as may be authorised.

All persons desiring to be admitted as workers, must send evidence of scientific training, qualification, and previous experience in original research along with a statement of the nature of the investigation they propose to undertake.

Candidates must apply for admission during the course of the preceding Term.

Forms of Application can be had from the ASSISTANT SECRETARY, Royal Institution, Albemarle Street, W.

BEDFORD COLLEGE, LONDON (FOR WOMEN),

YORK PLACE, BAKER STREET, W.

Principal: Miss ETHEL HURLBATT

The Session 1898-99 will begin on Thursday, October 6. Students are expected to enter their names between 8 and 4 p.m. on Wednesday, October 5.

Further information on application

BEDFORD COLLEGE, LONDON (FOR WOMEN),

YORK PLACE, BAKER STREET, W.

HYGIENE AND PUBLIC HEALTH

Course of Scientific Instruction, Practical and Theoretical, will be given on Tuesday, October 6, and extend over Three Terms. Further information on application to the PRINCIPAL, at the College.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

ELECTRICAL ENGINEERING

Professor ANDREW GRAY, LL.D., F.R.S., will begin, in OCTOBER next, a SYSTEMATIC COURSE OF INSTRUCTION in Electrical Measurement and Practical Electricity. The Physical Laboratory is fully equipped with a Compound Steam Engine, Dynamo, Transformer, Secondary Battery, and the most approved modern Measuring Instruments for all Branches of Electrical Engineering. Laboratory Fees at the rate of £1 12 per Term for six hours per week. Composition Fee for all College Lectures for the Session, £10.

Applications for Calendar, Prospectus, and general information to be made to

J. E. LLOYD, M.A., Secretary and Registrar

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

ASSISTANT LECTURER AND DEMONSTRATOR IN

ANATOMY.

The Council is prepared to appoint an ASSISTANT LECTURER and DEMONSTRATOR in ANATOMY, at a Stipend of £100 per Annum.

TEMPORARY ASSISTANT LECTURER AND DEMONSTRATOR IN PHYSIOLOGY.

The Council is prepared to appoint, for One Year, an ASSISTANT LECTURER and DEMONSTRATOR in PHYSIOLOGY at a Salary of £120.

Applications for these Posts, together with Testimonials, which need not be printed, to be sent to the undersigned until before July 1st.

J. AUSTIN JENKINS, B.A., Registrar
University College, Cardiff, July 7, 1898

THE WALSALE VICTORIA INSTITUTE.

The Technical Instruction Committee of the Walsale Victoria Institute require a DIRECTOR OF TECHNICAL INSTRUCTION, whose duties shall comprise the Organisation and Superintendence, under the Committee, of Classes in Science, Art, Literature, Music, and Technology, the Secretarial Work, and the Management of the Accounts of the Institute. The Director will be required to devote his whole time to the service of the Institute and must have a knowledge of the routine and regulations of the Science and Art Department.

Further particulars obtained on application to the undersigned, on receipt of stamped addressed foolscap envelope.

Applications endorsed "Director of Technical Instruction," stating age, experience, qualifications, with three Testimonials, and recent Photograph, must be sent to the CHAIRMAN of the TECHNICAL INSTRUCTION COMMITTEE, Walsale Victoria Institute, Walsale, before Thursday, the 28th day of July next.

AI FD BKCKETT, Secretary (per *lure*).

Walsale Victoria Institute, July 12, 1898

SWINDON AND NORTH WILTS TECHNICAL SCHOOL.

The Committee require the Services of a SCIENCE MASTER for Day and Evening Classes.

The Master will be required to teach Practical Geometry and such other subjects as may be arranged.

Preference will be given to a Candidate with qualifications in Mathematics and Physics.

Salary, £200 per annum.

Particulars and Forms of Application, which should be returned not later than July 29, may be obtained from the SECRETARY, Swindon and North Wiltshire Technical School, Victoria Road, Swindon, Wiltshire.

UNIVERSITY OF ST. ANDREWS. CHAIRS OF MATERIA MEDICA AND PATHOLOGY.

In accordance with the terms of Ordinance No. 47, St. Andrews No. 6, of the Commissioners under the Universities (Scotland) Act, 1850, the University Court will appoint PROFESSORS OF MATERIA MEDICA AND PATHOLOGY, who shall conduct Classes at Dundee qualifying for graduation in Medicine, the Appointments to date from October 1, 1898.

Applications, accompanied by thirty copies of testimonials, to be lodged, by August 31 next, with Mr. STEWART GRACE, Secretary of the University Court, from whom further information may be obtained.
St. Andrews, June 1898

THE MANCHESTER MUSEUM, OWENS COLLEGE.

The Position of ASSISTANT KEEPER in the Geological Department is vacant, owing to the appointment of Mr. Bolton to the Curatorship of the Bristol Museum. Salary, £30 a year.

Applications, with References, should be addressed, before September 1, to the KEEPER OF THE MUSEUM, The Owens College, Manchester.

The LECTURESHIP in ENGINEERING is Vacant. Salary, £250 per annum.

Applications to be sent in to the PRINCIPAL not later than August 9.

Statement of duties may be obtained upon application to
THOS. THORP, Secretary.

ELECTRICAL ENGINEERING.

THE ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTION, 8 CHARING CROSS ROAD, LONDON
(Proprietors—Syndicate of Electrical Engineers, Ltd.)

BOARD OF CONTROL.
The Rt. Hon. the Earl of CRAWFORD, K.T., F.R.S., Chairman
The Rt. Hon. Lord Castletown. Hugh Erat Harrison
The Hon. R. Brougham. Francis Ince
Robert Hammond. William O. Smith

Affords a Theoretical and Practical Training, and qualifies the Sons of Gentlemen for Appointments in Mechanical and Electrical Engineering. After the Preliminary Training in Theory at the Institution, Students go through a Practical Course, first in the Mechanical Engineering Works and subsequently the Electrical Works, the Institution being associated with over 50 leading Firms and Engineers for this purpose. They are thus brought directly into association with prominent Companies and Firms and secure an introduction to the Profession under the most favourable auspices. **APPOINTMENTS HAVE BEEN SECURED FOR OVER 80 PER CENT OF THE STUDENTS** who have completed their Course since the foundation of the Institution, and applications continue to be received for competent men. Prospectus on application.

URBAN DISTRICT OF HANDSWORTH IN THE COUNTY OF STAFFORD

The Technical Instruction Committee are desirous of receiving Applications for the Appointment of ASSISTANT SCIENCE MASTER at the Handsworth Technical School. Salary, £100 per Annum, increasing £10 per Year to £120. The gentleman appointed must be fully qualified to teach Physics and Chemistry, Geometry, Machine Construction and Drawing, and Applied Mechanics and Steam. An A.R.C.S. preferred. Applications, stating age, qualifications, and experience in Teaching, and whether willing to take other Science Subjects if required with copies of four recent Testimonials, to be sent by Post at the Council House, Handsworth (Staffordshire), on or before the 30th Instant.

The Committee will, after considering the Applications, request the attendance of such Candidates as it may select, and pay railway fares.

H. WARD, Honorary Secretary to the Committee
Council House, Soho Road, Handsworth, July 18, 1898

MERCHANT VENTURERS' TECHNICAL COLLEGE, BRISTOL.

JUNIOR FORM MASTER for the Boys School Wanted in September next. Salary, £150 to £170 a year. Applicants must state that they have read the printed particulars in regard to the Appointment, which can be obtained by sending a stamped addressed envelope to the RECTOR.

McGILL UNIVERSITY, MONTREAL.

Applications are invited for the Post of ASSISTANT PROFESSOR of CIVIL ENGINEERING. Candidates should have had Experience in Teaching, and must possess a thorough knowledge of the Theory of Structures and of Hydraulics. They should also be prepared to undertake the superintendence of Designing.

Apply at once, by letter, to the PRINCIPAL, 81 Iliffe Road, Oxford.

HARTLEY COLLEGE, SOUTHAMPTON.

Applications are invited for the Post of ASSISTANT LECTURER and DEMONSTRATOR in PHYSICS and ELECTRICAL ENGINEERING.

Salary, £120 per annum.

Applications must be received on or before Monday, August 8, 1898.

Particulars may be obtained on application to the CLERK.

SOUTH-WESTERN POLYTECHNIC, MANRESA ROAD, CHELSEA.

The Governing Body invite Applications for the Post of SENIOR DEMONSTRATOR of ELECTRICAL ENGINEERING. Initial Salary, £150 per annum.

For particulars send stamped and addressed envelope to the SECRETARY, not later than August 3.

UNIVERSITY COLLEGE OF SHEFFIELD.

The Council propose to appoint an ASSISTANT LECTURER in MATHEMATICS. Salary, £150. Applications to be made before July 25. Particulars from the REGISTRAR.

UNIVERSITY COLLEGE OF SHEFFIELD.

The Post of ASSISTANT LECTURER and DEMONSTRATOR of PHYSICS is Vacant. Salary, £150 per annum. Applications to be made before July 25. Particulars on application to the REGISTRAR.

BRUNT'S TECHNICAL SCHOOL, MANSFIELD.

A THIRD ASSISTANT MASTER Required, in common in Sept. To take part in the instruction of the Schools of Science. Experience in Physical Laboratory highly desirable. Salary, £75 per annum. Apply, with copies of Testimonials, to the HEADMASTER.

THE BRIDGES-LEE PHOTO-THEODOLITE

*The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys*

The Photo-Theodolite automatically records on the photograph all, or nearly all, the data necessary for the reduction of the photographs, including the Magnetic bearings,—thus considerably reducing the time spent and the risk of error in the interpretation of the photographs.

The Instrument is fitted with an Aluminium Body, 6-in. Azimuthal Circle, reading with Vernier to one minute of arc, 4-in. Compass, divided to half degrees. Telescope with erect and inverting Eyepieces, rapid Rectilinear Lens with Iris Diaphragm and Colour Screen, six double dark Slides in Mahogany Case, with Stand complete, £245.

Descriptive Pamphlets and Illustrated Description of the Instrument sent free on application.

THE

SULPHATE OF AMMONIA COMMITTEE OFFER

THE SUM OF 500 GUINEAS

To be given for the best Essay on the following subject

"THE UTILITY OF SULPHATE OF AMMONIA
IN AGRICULTURE."

The subject to be treated from a practical and scientific point of view

The Committee has secured the services of Mr. William C. Little, Member of the late Royal Commissions on Agriculture, and Dr. Voelcker, Consulting Chemist to the Royal Agricultural Society of England, to act as Judges of the essays sent in. In the event of any difference arising, Mr. Samuel Rowlandson, a Member of the Council of the Royal Agricultural Society of England, will act as referee.

The essays must be in the English language, and written on one side of the paper only; they must further bear a distinguishing motto or *nom de plume*, but not the names of the authors.

Each author, when sending in his essay, must at the same time write his name and address on a slip, which he shall enclose in a separate envelope, seal the latter, and write outside it the motto or *nom de plume* he adopts for his essay. The essay and the envelope containing the slip to be sent in, under one cover, to the undersigned.

The envelopes containing the names of the authors will be opened in the presence of the Committee after the judges have made their award.

All essays must be in the hands of the undersigned not later than November 15, 1898. The selected essay will become the property of the Committee, who reserve to themselves the right to make such use of it as they think fit.

The Committee also reserves to itself the right to purchase for a sum not exceeding fifty guineas any of the other essays.

W. G. SLADEN (Chairman), 4 Fenchurch Avenue, London, E.C.

(PATENT)

ROSS' COMBINATION LANTERN.

This instrument has been designed to meet the requirements of those who desire an apparatus mainly for ordinary Projection with occasional Enlargement, and also of others whose object is primarily enlarging, but who may occasionally wish to utilise the same instrument for projecting ordinary lantern slides.

The following are some of the uses to which this Lantern may be put—Projection of Lantern Slides, Projection of 1 Plate Transparencies, Enlarging from 1 Plate, Enlarging from 1 Lantern Slide, Enlarging from portions of large Plates, Projection of 41 Parallel Beams, Projection of 31 Parallel Beams, the Illumination of Tableaux, &c., General Science Work.

PRICES—

Complete with two condensers and objective (better than the usual "best quality" commercial objective), in neat case, without jet, but including lamp for enlarging.

£14 : 10 : 0. Jets extra, from 25/-

CARD AND SLIP FILES.

Portion of Card File

The Ceres Card Files in Cabinets (with rod) for Library Catalogues, and in Boxes and Trays (without the rod) for other purposes, constitute the latest development of the Card System

The Bishop of Bristol:—"The convenience of the Writing Table with 'Ceres' Files is beyond words. So far as I can keep pace with my correspondence, there is never anxiety as to where a letter is, and the drawer with cards for notes of references, speeches, sermons, &c., makes me perpetually regret that I had not such a thing twenty years ago."

Sir H. H. Bemrose, M.P.:—"I am using the Card Box daily for a literary purpose, and I find it simply invaluable. As it lies on the table entries are made at the moment under their proper heads, and the facility of reference is such as no other mode of indexing I am aware of can touch."

For other varieties and sizes of Box Files, Cabinets, Writing Tables, Standing Desks, Card Files, &c., see Explanatory Pamphlet, Post Free.

NEWMAN & GUARDIA, Ltd.,
90 & 92 Shaftesbury Avenue, London, W

JAS. J. HICKS,

8, 9 & 10 HATTON GARDEN, LONDON,

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special construction, and a simple and accurate arterial pressure gauge. It is marvellously sensitive, and consists of a metal tambour, the expansion of which is exhibited in a highly magnified form by means of an index or pointer which travels round a dial. This dial is graduated in millimetres of mercury. The armlet pump and pressure gauge, when not in use, fit conveniently into a leather case. By means of this instrument we believe that the arterial pressure can be taken in man as rapidly, simply, and accurately as the temperature can be taken with the clinical thermometer.

Price 25s. Spare Bag and Tube, 5s.
The instrument has a 5-in. Dial, and is packed in a
neat morocco Case with Handles.
FULLER PARTICULARS ON APPLICATION.

Proprietor—J. TRUSLOVE.

THE SCIENTIFIC MAN'S, NATURALIST'S, AND TRAVELLER'S CAMERA

IS THE

Stereoscopic Company's BINOCULAR,

Because when ready to take is Pictures it weighs 19 ounces only.

It is used like a Field Glass. Takes instantaneous and time exposures. Gives Pictures 2 in. by 3 in. when used with the simple printing and enlarging apparatus. Price 25s. only. Complete with enlarging apparatus, £10 10s. FREE Lessons to Purchasers.

From R. BOWDLER SHARPE, Esq., LL.D., Assistant Keeper, Zoological Department, British Museum.

"I have received the remainder of the proofs of my photographs, and I must say that I am delighted with them. I consider it one of the best day's work I ever did when I bought one of your 'Binocular' Camera. The ease with which it is worked, and the excellent results obtained, make it a most pleasurable accompaniment of a summer's outing, and, in my case, 90 per cent. of my Norway photographs have come out beautifully, while even the small remainder cannot be considered failures. I think this is a grand result, when you remember that I had little or no experience of photography, and had only time for an hour's instruction in your rooms the day before I sailed, and, further, that I had to make my own dark rooms in Norway in the best way I could. I am looking forward so having much pleasure this summer from the faithful 'Binocular,' and I have recommended it to all my friends."

Mahogany Body and Oxymethylene Jet, in Case, £65 10s. Also several OIL LANTERNS from £1 to £25.

E. G. WOOD, OPTICIAN,
 74 CHEAPSIDE, LONDON.

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.

The Photo Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduction
of the photographs,
including the Magnetic
bearings, — thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs.

The instrument is fitted with
an Aluminium Body, 6-in.
Azimuthal Circle, reading with
Vernier to one minute of arc,
4-in. Compass, divided to half
degrees. Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £46.

Descriptive Pamphlets and Illustrated Description
of the instrument sent free on application.

"Instrument Company, Ltd., Cambridge."

THE SULPHATE OF AMMONIA COMMITTEE OFFER THE SUM OF 500 GUINEAS

To be given for the best Essay on the following
subject:—

"THE UTILITY OF SULPHATE OF AMMONIA IN AGRICULTURE."

The subject to be treated from a practical and scientific
point of view.

The Committee has secured the services of Mr William C Lisle,
Member of the late Royal Commissions on Agriculture, and Dr Voelcker,
Consulting Chemist to the Royal Agricultural Society of England, to act
as Judges of the essays sent in. In the event of any difference arising, Mr
Samuel Rowlandson, a Member of the Council of the Royal Agricultural
Society of England, will act as referee.

The essays must be in the English language, and written on one side of
the paper only, they must further bear a distinguishing motto or *nom de plume*,
but not the names of the authors.

Each author, when sending in his essay, must at the same time write
his name and address on a slip, which he shall enclose in a separate
envelope, seal the letter, and write outside the motto or *nom de plume*
he adopts for his essay. The essay and the envelope containing the
slip to be sent in, under one cover, to the undersigned.

The envelopes containing the names of the authors will be opened
in the presence of the Committee after the judges have made their
award.

All essays must be in the hands of the undersigned not later than
November 15, 1898. The selected essay will become the property of
the Committee, who reserve to themselves the right to make such use
of it as they think fit.

The Committee also reserves to itself the right to purchase for a sum
not exceeding fifty guineas any of the other essays.

THE NEW STIGMATIC LENS.

SERIES II 7/6

BRITISH DESIGN AND WORKMANSHIP.

is the best All-round Lens for either Professional or Amateur use.

Each lens will give perfect definition with full aperture to the extreme corners of the plate it is sold to cover, with smaller stops it will cover at least two sizes larger, giving perfect sharpness all over the plate, and thus becoming a wide-angle lens of the highest excellence. Either combination may be used separately giving foci of about 14 and 2 times the length of that of the lens when used intact. The advantage of this being able to choose the best point of view, irrespective of distance, will be at once apparent to the artistic worker.

EQUIVALENT TO FOUR LENSES AT THE PRICE OF ONE.

Eleven Sizes are now ready from 3 1/2 to 18 inches eq. focus.

CITY AND GUILDS CENTRAL TECHNICAL COLLEGE.

(EXHIBITION ROAD, S.W.)

A College for higher Technical Instruction for Students not under 16 preparing to become Civil, Mechanical or Electrical Engineers, Chemical and other Manufacturers, and Teachers. Fees for a full Associateship Course, £15 per Session. Professors —

Civil and Mechanical Engineering W. C. UNWIN, F.R.S., M. Inst. C.E.
Physics and Electrical Engineering W. E. AYTON, F.R.S., Past Pres. Inst. E.E.
Chemistry H. E. ARMSTRONG, Ph.D., I.L.D., F.R.S.
Mechanics and Mathematics O. HENRICI, Ph.D., I.L.D., F.R.S.

CITY AND GUILDS TECHNICAL COLLEGE, FINSBURY.

(LEONARD STREET, CITY ROAD, E.C.)

Provides Courses of Intermediate Instruction for Day Students not under 14 years of age, preparing to enter Engineering and Chemical Industries. Fees, £15 per Session. Professors —

Physics and Electrical Engineering S. P. THOMPSON, D.Sc., F.R.S.
Mechanical Engineering and Mathematics W. E. DALRY, M.A., B.Sc., M.I.M.E.
Chemistry R. MAIHOLA, F.R.S., F.I.C.

JOHN WATNEY, Hon. Secretary

City and Guilds of London Institute,
Gresham College, Basinghall Street, E.C.

UNIVERSITY COLLEGE OF NORTH WALES (BANGOR).

SESSION 1898-99 will open on TUESDAY, OCTOBER 4.
DEPARTMENTS OF PHYSICS, CHEMISTRY, AND BIOLOGY

PHYSICS.

Prof A. GRAY, M.A., LL.D., F.R.S.
Assistant Lecturers and Demonstrators, T. C. BAILLIE, M.A., B.Sc., and E. TAYLOR JONES, D.Sc.

CHEMISTRY.

Prof J. J. DORRIS, M.A., D.Sc.
Assistant Lecturer and Demonstrator, F. MARSDEN, M.Sc., Ph.D. (Haidelsberg)

BIOLOGY.

Botany—Prof R. W. PHILLIPS, M.A., B.Sc.
Assistant Lecturer and Demonstrator, J. LLOYD WILLIAMS

Zoology—Prof PHILIP J. WHITE, M.B., F.R.S.E.

The Classes and Laboratory Courses of this College are arranged to suit the requirements of Students of Practical Science, as well as of Students preparing for University and other Examinations. The Lectures in Chemistry, Physics, Botany, and Zoology, are recognised by the Universities of Edinburgh and Glasgow as qualifying for the Medical Degrees of those Universities. One *Anatomical Medicine* may be taken at this College.

The extensive Laboratories (Physical, Chemical, and Biological) are fully equipped for Study and Research, and in the Physical Department special provision has been made for the Teaching of Electrical Engineering. A Special Course has been arranged in this subject.

Inclusive Tuition Fee, £11 12

LABORATORY FEES (per Term)

on the scale of £1 12 for six hours a week, in each Department.

A considerable number of Scholarships and Exhibitions are open for competition at the beginning of each Session, and several are awarded at the close of each Session on the result of the year's work.

For full information as to Science and Arts Courses, apply for Prospectus to the Secretary and Registrar, J. E. LLOYD, M.A.

BALLIOL COLLEGE, CHRIST CHURCH, AND TRINITY COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIPS AND EXHIBITIONS

A Combined Examination for Natural Science Scholarships and Exhibitions will be held by the above Colleges, beginning on TUESDAY, NOVEMBER 15, 1898.

Three Scholarships and Two Exhibitions will be offered, the Scholarships being worth £80 a year.

The Subjects for Examination will be Physics, Chemistry, and Biology, but Candidates will not be expected to offer themselves in more than two of these.

Particulars may be obtained by application to
Christ Church, Oxford A. VERNON HARCOURT

OWENS COLLEGE, VICTORIA UNIVERSITY, MANCHESTER.

PROSPECTUSES for the Session 1898-9 will be forwarded on application —

- I — DEPARTMENT OF ARTS, SCIENCE, and LAW, and DEPARTMENT FOR WOMEN.
- II — DEPARTMENT OF MEDICINE
- III — EVENING and POPULAR COURSES
- Special Prospectuses can also be obtained of —
- IV — DEPARTMENT OF ENGINEERING
- V — DEPARTMENT OF LAW
- VI — DEPARTMENT OF PUBLIC HEALTH
- VII — DENTAL DEPARTMENT
- VIII — PHARMACEUTICAL DEPARTMENT, and
- IX — FELLOWSHIPS, SCHOLARSHIPS, EXHIBITIONS, and

MASON UNIVERSITY COLLEGE, BIRMINGHAM.

FACULTIES OF ARTS AND SCIENCE

SESSION 1898-9

THE NEXT SESSION COMMENCES ON TUESDAY, OCTOBER 4.

Complete Courses of Instruction are provided for the various Examinations in Arts and Science, and the Preliminary Scientific (M.B.) Examination of the University of London, for Students of Civil, Mechanical, and Electrical Engineering, and for those who desire to obtain an acquaintance with some branch of Applied Science, including Chemistry, Metallurgy, &c. Students may, however, attend any Class or combination of Classes.

(There is also a Faculty of Medicine, a Syllabus of which, containing full particulars, may be had gratis from Messrs. CORNISH, New Street.)
A SYLLABUS of the Arts and Science Faculties, with full information as to the various Lectures and Laboratory Courses, Lecture Days and Hours, Fees, Entrance and other Scholarships, Prizes, &c., may be had gratis from Messrs. CORNISH, New Street, Birmingham, or on application to the Registrar, at the College.

HERIOT-WATT COLLEGE, EDINBURGH.

F. GRANT OGILVIE, M.A., B.Sc., F.R.S.E., Principal.
DAY CLASSES—SESSION 1898-99.

The Session extends from Tuesday, October 4, 1898, to Friday, June 3, 1899.

These Classes provide Courses of Study extending over one or more years, suitable for Students who have previously passed through the Curriculum of a Second School. The principal Courses are — Physical and Chemical, Mechanical Engineering and Electrical Engineering. There are also Classes in French, German, Drawing, and Practice of Commerce. Class Fees, from £12 12 to £42 42. Session Fee, £10 10.

There is also a Preparatory Course of Instruction for Agricultural Students. Session Fee, £5 5. An extract from the Calendar of the College, giving particulars of the Day Classes and of the various Appliances, Laboratories, and Workshops available for instruction, may be had on application to the Librarian, at the College, or to the Treasurers of George Heriot's Trustees.

DAVID LEWIS, Treasurer
Treasurer's Chambers, 20 York Place, Edinburgh,
July 15, 1898

OWENS COLLEGE, VICTORIA UNIVERSITY, MANCHESTER.

CHEMISTRY COURSE

Full particulars of this Course, qualifying for the Victoria University Degrees in Chemistry and the College Technological Chemistry Certificate, will be forwarded on application.
The Session commences on October 4.

S. CHAFFERS, Registrar.

CIVIL SERVICE COMMISSION.

FORTHCOMING EXAMINATION.

Junior Assistant in the Science Branch of the South Kensington Museum (18-25), September 25.

The date specified is the latest at which Applications can be received. They must be made on forms to be obtained, with particulars, from the SECRETARY, Civil Service Commission, London, S.W.

ELECTRICAL ENGINEERING.

THE ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTE, 3 CHANCERY CROSS ROAD, LONDON
(Proprietors—Syndicate of Electrical Engineers, Ltd.)

BOARD OF CONTROL
The Rt. Hon. the Earl of CRAWFORD, K.T., F.R.S., Chairman
The Rt. Hon. Lord Castletown Hugh Esqr. Harrison
The Hon. R. Brougham Francis Ince
Robert Hammond William O. Smith

Affords a Theoretical and Practical Training, and qualifies the Sons of Gentlemen for Appointments in Mechanical and Electrical Engineering After the Preliminary Training in Theory at the Institution, Studied through a Practical Course, first in the Mechanical Engineering Works and subsequently the Electrical Works, the Institution being associated with over 50 leading Firms and Engineers for this purpose. They are thus brought directly into association with prominent Companies and Firms, and secure an introduction to the Profession under the most favourable auspices. **APPOINTMENTS HAVE BEEN SECURED FOR OVER 80 PER CENT OF THE STUDENTS** who have completed their Course since the foundation of the Institution, and applications continue to be received for competent men. Prospectus on application.

VICTORIA UNIVERSITY**THE YORKSHIRE COLLEGE, LEEDS.**
DEPARTMENT OF MINING

The Council of the Yorkshire College, Leeds, invite Applications for the appointment of PROFESSOR OF MINING at a Stipend of £700 and half the Class Fee. The Professor will be required to conduct classes in Coal and Metalliferous Mining, both for Students attending a systematic Course extending over three years, and for persons engaged in Collieries and attending one or two Classes per week. The Professor will have liberty to undertake private practice to a limited extent. Applications will be received up to August 15, and the Professor will be required to enter upon his duties on October 1, 1898.

CITY OF BIRMINGHAM
MUNICIPAL TECHNICAL SCHOOL.

The Corporation require the services, in September next, of an ASSISTANT MASTER for the Lower Forms of the Day School, to take English, and Elementary Mathematics and French. Salary, £100 per annum.

Full particulars and form of application will be forwarded on receipt of a stamped addressed envelope. The last date for sending in applications is August 14.

GEO. MILLOR, Secretary

Office of the School, Suffolk Street
July 25, 1898

TECHNICAL COLLEGE,
HUDDERSFIELD

The LECTURESHIP IN ENGINEERING is Vacant. Salary, £250 per annum.

Applications to be sent in to the PRINCIPAL not later than August 9. Statement of duties may be obtained upon application to THOS. THORP, Secretary.

TECHNICAL COLLEGE,
HUDDERSFIELD.

The ASSISTANT LECTURESHIP in English, Latin and French is Vacant. Salary, £100 per annum. Applications to be sent in to the PRINCIPAL not later than August 16. Statement of duties may be obtained upon application to THOS. THORP, Secretary.

HARTLEY COLLEGE,
SOUTHAMPTON.

Applications are invited for the Post of ASSISTANT LECTURER and DEMONSTRATOR IN PHYSICS and ELECTRICAL ENGINEERING. Salary, £130 per annum.

Applications must be handed on or before Monday, August 5, 1898. Particulars may be obtained on application to the CLERK.

THE MANCHESTER MUSEUM,
OWENS COLLEGE

The Position of ASSISTANT KEEPER in the Geological Department is Vacant, owing to the appointment of Mr. Bolton to the Curatorship of the Bristol Museum. Salary, £120 to £150. Applications, which are to be sent in not later than August 24, should be made on forms supplied by the KEEPER OF THE MUSEUM, The Owens College, Manchester.

UNIVERSITY COLLEGE,
NOTTINGHAM.

A LECTURER and DEMONSTRATOR in PHYSICS will be required in October. Salary, £120 to £150. Applications, which are to be sent in not later than August 24, should be made on forms supplied by the SECRETARY.

The Valuable Collection of Indian and Burmese Swords, Daggers, Guns, Shields, Pistols, Lances and Other Weapons, also Gods, Tanks, Vases, Churns, a splendid Gong on Massive Carved Stand, Trophies of Armour, &c., the property of the late General Sir H. P. Pownall. Also Relics, Antiquities, a Collection of Caskets from the Admiralty Islands, Ancient Implements, a valuable Sandwich Island Feather Cloak, a Collection of Royal Hair, &c.

MR. J. C. STEVENS will Sell the above by Auction at his Great Rooms, 38 King Street, Covent Garden, on **TUESDAY** next, **AUGUST 9**, at half past 12 precisely. On view the Day prior, to till 4, and Morning of Sale, and Catalogues had.

THE BRIDGES-LEE PHOTO-THEODOLITE

*The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.*

The Photo Theodolite automatically records on the photograph all, or nearly all, the data necessary for the reduction of the photographs, including the Magnetic bearings,—thus considerably reducing the time spent and the risk of error in the interpretation of the photographs.

The instrument is fitted with an Aluminium Body, 6-in. Azimuthal Circle, reading with Vernier to one minute of arc, 4-in. Compass, divided to half degrees. Telescope with erect and inverting Eyepieces, rapid Rectilinear Lens with Iris Diaphragm and Colour Screen, six double dark Slides in Mahogany Case, with Stand complete, £65.

CARD AND SLIP FILES.

Portion of Card File

The Ceres Card Files in Cabinets (with rod) for Literary Catalogues, and in Boxes and Trays (without the rod) for other purposes, constitute the latest development of the Card System

The Bishop of Bristol:—"The convenience of the Writing Table with 'Ceres' Files is beyond words. So far as I can keep pace with my correspondence, there is never anxiety as to where a letter is, and the drawer, with cards for notes of references, speeches, sermons, &c., makes me perpetually regret that I had not such a thing twenty years ago."

Sir H. H. Bemrose, M.P.:—"I am using the Card Box duly for a literary purpose, and I find it simply invaluable. As it lies on the table, entries are made at the moment under their proper heads, and the facility of reference is such as no other mode of indexing I am aware of can touch."

NEWMAN & GUARDIA, Ltd.,
90 & 92 Shaftesbury Avenue, London, W

JAS. J. HICKS, 8, 9 & 10 HATTON GARDEN, LONDON;

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special construction, and a simple and accurate arterial pressure gauge. It is marvellously sensitive, and consists of a metal tambour, the expansion of which is exhibited in a highly magnified form by means of an index or pointer which travels round a dial. This dial is graduated in millimetres of mercury. The airtight pump and pressure gauge, when not in use, fit conveniently into a leather case. By means of this instrument we believe that the arterial pressure can be taken in man as rapidly, simply, and accurately as the temperature can be taken with the clinical thermometer.

Price £5. Spare Bag and Tube, 5s.

The instrument has a 6-in. Dial, and is packed in a
Neat Morocco Case with Handle.

BROWNING'S PLATYSCOPIC LENS.

With Larger Angles, Increased Field, and Improved Definition

Engraved Real Size
AN ACHROMATIC COMBINATION,
COMBINING THE DEFINITION OF A MICROSCOPE WITH THE PORTABILITY OF A POCKET LENS
If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do).—GRANT ALLEN in *Knowledge*
The Platyscopic Lens is invaluable to botanists, mineralogists and entomologists as it focuses about three times as far from the object as the Coddington Lenses. This allows opaque objects to be examined easily.
The Platyscopic Lens is made of four degrees of power, magnifying respectively 10, 15, 20 and 30 diameters the lowest power having the largest field. It is the best adapted for general use.
The Lenses are set in Elbow-like Cells and mounted in Tortoiseshell Frames
Price of the Platyscopic Lens mounted in Tortoiseshell magnifying either 10, 15, 20, or 30 diameters; 18s 6d each power

ENGINEERING AND CHEMISTRY CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Instruction at the Institute's CENTRAL TECHNICAL COLLEGE (Exhibition Road) are for Students not under 16 years of age; those at the Institute's TECHNICAL COLLEGE, FINCHBURY, are of an Intermediate Grade for Students not under 14 years of age. The Entrance Examinations to both Colleges are held in September, and the Sessions commence in October. Particulars of the Entrance Examinations, Scholarships, Fees, and Courses of Study, may be obtained from the respective Colleges, or from the Head Office of the Institute, Gresham College, Basinghall Street, E.C.

CITY AND GUILDS CENTRAL TECHNICAL COLLEGE.

(EXHIBITION ROAD, S.W.)

A College for higher Technical Instruction for Students not under 16 years of age, to become Civil, Mechanical or Electrical Engineers, Chemical and other Manufacturers, and Teachers. Fees for a full Associateship Course, £25 per Session. Professors:—

Civil and Mechanical Engineering W. C. UNWIN, F.R.S., M. Inst. C.E.
Physics and Electrical Engineering W. E. AYTON, F.R.S., Past Pres. Inst. E.E.
Chemistry H. E. ARMSTRONG, Ph.D., LL.D., F.R.S.
Mechanics and Mathematics O. HENRICI, Ph.D., LL.D., F.R.S.

CITY AND GUILDS TECHNICAL COLLEGE, FINCHBURY.

(LEONARD STREET, CITY ROAD, E.C.)

Provides Courses of Intermediate Instruction for Day Students not under 12 years of age, preparing to enter Engineering and Chemical Industries. Fees, £15 per Session. Professor:—

Physics and Electrical Engineering S. P. THOMPSON, D.Sc., F.R.S.
Mechanical Engineering and Mathematics W. E. DALY, M.A., B.Sc., M.I.M.E.
Chemistry R. MELDOLA, F.R.S., F.I.C.

JOHN WATNEY, Hon. Secretary

City and Guilds of London Institute,
Gresham College, Basinghall Street, E.C.

ST. MARY'S HOSPITAL MEDICAL SCHOOL,

PADDINGTON, W.

The WINTER SESSION begins on October 3, with an Introductory Address, at 3 p.m., by Dr. CALVEY. The Annual Dinner will be held in the Evening at the King's Hall, Holborn Station, Mr. J. N. MOWAT, J.P., in the Chair.

ENTRANCE SCHOLARSHIPS IN NATURAL SCIENCE.

One of £144, Two of £72 15s., One of £52 10s., Two of £37 15s. (these two open to Students from Oxford and Cambridge) will be awarded by Examination on September 21 and 22.

There are Sixteen Resident Appointments in the Hospital open to Students without expense. The School provides complete preparation for the Higher Examinations and Degrees of the Universities. Special attention is directed to the fact that the authorities of the Medical School have for the first time thrown open all the Special Classes for the Higher Examinations free to Students.

The Residential College is at present at 33 and 35 Westbourne Terrace. W. Terms may be had on application to the Warden, Mr. H. S. COLLIER.

NEW OUT-PATIENTS' DEPARTMENT

The new Out-Patients' Department, which covers an area of over 10,000 superficial square feet, was opened in May. It occupies the entire ground floor of the new Clarence Wing, which, when completed, will also provide additional Wards and a Residential College for Medical Officers and Students.

ENLARGEMENT OF THE MEDICAL SCHOOL.

The New School Buildings and Laboratories, begun in the Midsummer vacation of last year, were completed by the middle of the Winter Session. The Physiological Laboratories have been further increased, and form a series of rooms which occupy the whole of the first floor of both the old and new buildings.

A fresh Laboratory, fitted with electric light and all modern improvements, for the study of Biology, Pathology, and Bacteriology, has been added.

All the buildings hitherto used for the Out-Patients' Department of the Hospital have been appropriated to the Medical School for purposes of New Laboratories, Classrooms, and a New Museum. A complete re-organization of the Pathological Department has lately been made, with provision of extensive New Laboratories for Pathology and Bacteriology, and an improved Museum for Pathological Specimens, with a special Anatomical Department.

For Prospectus apply to Mr. F. H. MADSEN, School Secretary.

G. P. FIELD, Dean
A. P. LUFF, M.D., Sub-Dean

UNIVERSITY COLLEGE OF NORTH WALES (BANGOR).

SESSION 1898-99 will open on TUESDAY, OCTOBER 4.
DEPARTMENTS OF PHYSICS, CHEMISTRY, and BIOLOGY.

PHYSICS — Prof. A. GRAY, M.A., LL.D., F.R.S.
Assistant Lecturers and Demonstrators, T. C. BAILLIE, M.A., B.Sc., and E. TAYLOR JONES, D.Sc.
Prof. J. J. DORRIS, M.A., D.Sc.
CHEMISTRY — Assistant Lecturer and Demonstrator, F. MARSDEN, M.Sc., Ph.D. (Heidelberg).
Botany—Prof. R. W. PHILLIPS, M.A., B.Sc.
BIOLOGY — Assistant Lecturer and Demonstrator, J. LLOYD WILLIAMS.
Zoology—Prof. PHILIP J. WHITE, M.B., F.R.S.E.

The Classes and Laboratory Courses of this College are arranged to suit the requirements of Students of Practical Science, as well as of Students preparing for University and other Examinations. The Lectures in Chemistry, Physics, Botany, and Zoology, are recognised by the Universities of Edinburgh and Glasgow as qualifying for the Medical Degrees of those Universities. One *Novus Medicus* may be taken at this College.

The extensive Laboratories (Physical, Chemical, and Biological) are fully equipped for Study and Research, and in the Physical Department special provision has been made for the Teaching of Electrical Engineering. A Special Course has been arranged in this subject.

Inclusive Tuition Fee, £11 1s.

LABORATORY FEES (per Term)

on the scale of £1 1s. for six hours a week, in each Department.
A considerable number of Scholarships and Exhibitions are open for competition at the beginning of each Session, and several are awarded at the close of each Session on the result of the year's work.
For full information as to Science and Arts Courses, apply for Prospectus to the Secretary and Registrar, J. E. LLOYD, M.A.

UNIVERSITY COLLEGE, LONDON.

The SESSION OF THE FACULTIES OF ARTS and LAWS and of SCIENCE (including the Indian and Oriental Studies and the Department of Fine Arts) will begin on OCTOBER 3. The Introductory Lecture will be given, at 3 p.m., by Professor J. SULLY, M.A., LL.D.

	R. F. ST. A. ST. JOHN, M.A.

Students of both sexes are admitted. There is no Entrance examination. Scholarships, &c., of the value of £500 are offered for competition annually. The Regulations as to Regulations and further information as to Classes, Prizes, &c., may be obtained from

J. M. HORSBURGH, M.A., Secretary

UNIVERSITY COLLEGE, NOTTINGHAM.

A LECTURER and DEMONSTRATOR in PHYSICS will be required in October. Salary, £1500 a Year. Applications, which are to be sent in not later than August 24, should be made on forms supplied by the SECRETARY.

LATEST PUBLICATIONS OF THE ZOOLOGICAL SOCIETY OF LONDON

PROCEEDINGS OF THE ZOOLOGICAL SOCIETY OF LONDON, 1898 Part II. Containing Papers read at the Scientific Meetings held in March and April 1898. With Nine Plates. Price to Fellows, 9s.; to the Public, 12s.

TRANSACTIONS, Vol. XIV., Part 7, containing Papers "On the Lepidoptera of the Amazon," by Dr. Emil A. Goeldi, C.M.Z.S., with Two Plates, and "On a Collection of Fishes from the Rio Jurua, by G. A. Boulenger, F.R.S., F.Z.S., with Four Plates. Price to Fellows, 11s. 3d.; to the Public, 15s.

To be obtained at the Society's Office (5, Hanover Square, W.), or through any Bookseller.

GUY'S HOSPITAL MEDICAL SCHOOL.

The WINTER SESSION will begin on MONDAY, OCTOBER 3. Entrance Scholarships of the combined value of £400 are awarded annually, and numerous Prizes and Medals are open for Competition by Students of the School.

The number of Patients treated in the Wards during last year exceeded 6000.

All Hospital Appointments are made strictly in accordance with the merits of the candidates, and without extra payment. There are all Resident Appointments open to Students of the Hospital annually without payment of additional fee, and numerous Non-resident Appointments in the General and Special Departments. The Queen Victoria Ward, recently re-opened, will provide additional accommodation for Gynaecological and Maternity cases.

The College accommodates 60 Students, under the supervision of a Resident Warden.

The Dental School provides the full Curriculum required for the L.D.S. England.

The Clubs Union Athletic Ground is easily accessible.

A Handbook of Information for those about to enter the Medical Profession will be forwarded on application.

For the Prospectus of the School, containing full particulars as to Fees, Course of Study advised, Regulations of the College, &c., apply, personally or by letter, to the DEAN, Guy's Hospital, London Bridge, S.E.

LIVERPOOL SCHOOL BOARD

The Board require, as soon as possible, the services of an ASSISTANT SCIENCE DEMONSTRATOR. The person appointed must be qualified to take part in the Experimental Science Teaching (Mechanics, Chemistry, and Physics) given in the Board Schools. Salary, £100 first year, rising in four years to £120, with an extra annual payment from £35 to £41 if the applicant holds Science and Art Certificates and University Distinctions, and also a small proportion of the Grant received for the Classes if any, taught under the Science and Art Department.

Applications, stating age, qualification, and experience, must be received not later than Monday, August 23, addressed to

EDWARD M. HANCE, Clerk to the Board

School Board Offices, Liverpool, August 9, 1898

THE YORKSHIRE COLLEGE, LEEDS.

An ASSISTANT LECTURER and DEMONSTRATOR IN PHYSICS will be required at the beginning of next Session.

Applications will be received up to September 3 by the REGISTRAR of the College, from whom further particulars may be obtained.

UNIVERSITY COLLEGE, BRISTOL.

CHEMICAL DEPARTMENT.

Professor—SYDNEY YOUNG, D.Sc., F.R.S.

Lecturer—FRANCIS E. FRANCIS, B.Sc., Ph.D.

Demonstrator—D. H. JACKSON, M.A., B.Sc., Ph.D.

The SESSION 1898-99 begins on October 4. Lectures on Inorganic, Organic and Advanced Chemistry will be delivered during the Session. The Laboratories are fitted with the most recent improvements for the study of Practical Chemistry in all its branches. In the Evening the Laboratory is opened and Lectures on Chemistry, at reduced fees, are delivered. Several Scholarships are tenable at the College.

CALENDAR, containing full information, price 1s. (by Post 1s. 6d.)

For Prospectus and further particulars apply to JAMES RAPIN, Secretary.

UNIVERSITY COLLEGE OF SHEFFIELD.

SESSION 1898-99.

Departments of ARTS AND SCIENCE begin OCTOBER 5.

ENSOR DRURY, Registrar

HARTLEY COLLEGE, SOUTHAMPTON.

Applications are invited for the Post of ASSISTANT LECTURER and DEMONSTRATOR IN PHYSICS and ELECTRICAL ENGINEERING.

Salary, £120 per annum.

Applications must be received on or before Monday, August 8, 1898.

Particulars may be obtained on application to the CLERK.

TECHNICAL COLLEGE, HUDDERSFIELD.

The ASSISTANT LECTURESHIP in English, Latin and French is Vacant. Salary, £120 per annum. Applications to be sent in to the Principal not later than August 16. Statement of duties may be obtained upon application to

THOS THORP, Secretary

PHYSICAL DEMONSTRATOR (Camb

and Honn), aged Twenty-two, desires Re-engagement. Experience in Coll. of Sc.—Address, "O. N., NATURA OFFICE."

WANTED.—CHIEF CHEMIST and

MANAGER of WORKS, by a leading London Firm of Manufacturing Chemists employing several hundred people. The qualifications necessary for the position are: high and well-grounded scientific knowledge and attainments, good practical experience in carrying out manufacturing processes, exceptional powers of organisation and administration, tact, good judgment, capability to select and control scientific workers engaged in the manufacture of fine medicinal chemicals and pharmaceutical products. A gentleman with University training and Degrees preferred. The position commands a liberal salary. Replies will be treated in the strictest confidence if so desired. Address, stating age, qualifications, and experience, to "Manager," c/o Messrs MARKBY, STUART, & CO., 37 Coleman Street, London.

MASON UNIVERSITY COLLEGE, BIRMINGHAM.

FACULTIES OF ARTS AND SCIENCE.

SESSION 1898-99

THE NEXT SESSION COMMENCES ON TUESDAY, OCTOBER 4.

Complete Courses of Instruction are provided for the various Examinations in Arts and Science, and the Preliminary Scientific (M.B.) Examination of the University of London, for Students of Civil, Mechanical, and Electrical Engineering, and for those who desire to obtain an acquaintance with some branch of Applied Science, including Chemistry, Metallurgy, &c. Students may, however, attend any Class or combination of Classes.

(There is also a Faculty of Medicine; a Syllabus of which, containing full particulars, may be had gratis from Messrs CORNUM, New Street.)

A SYLLABUS of the Arts and Science Faculties, with full information as to the various Lecture and Laboratory Courses, Lecture Days and Hours, Fees, Entrance and other Scholarships, Prizes, &c., may be had gratis from Messrs CORNUM, New Street, Birmingham, or on application to the REGISTRAR, at the College.

HERIOT-WATT COLLEGE, EDINBURGH.

F. GRANT OGILVIE, M.A., B.Sc., F.R.S.E., Principal.

DAY CLASSES—SESSION 1898-99

The Session extends from Tuesday, October 4, 1898, to Friday, June 2, 1899.

These Classes provide Courses of Study extending over one or more years, suitable for Students who have previously passed through the Curriculum of a Secondary School. The principal Courses are—Physical and Chemical, Mechanical Engineering and Electrical Engineering. There are also Classes in French, German, Drawing, and Practice of Commerce. Class Fees, from £4 1s. to £4 4s. Session Fee, £10 10s.

There is also a Preparatory Course of Instruction for Agricultural Students. Session Fee, £3 5s. An extract from the Calendar of the College, giving particulars of the Day Classes, and of the various Appointments, Laboratories, and Workshops available for Instruction, may be had on application to the LIBRARIAN, at the College, or to the TREASURER of George Heriot's Trust.

DAVID LEWIS, Treasurer

Treasurer's Chambers, 20 York Place, Edinburgh,

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.

The Photo-Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduction
of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs.

The instrument is fitted with
an Aluminium Body, 6-in.
Azimuthal Circle, reading with
Vernier to one minute of arc,
4-in. Compass, divided to half
degrees. Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six
double dark Slides in Mahogany
Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description
of the instrument sent free on application.

FACULTIES OF ARTS AND SCIENCE SESSION 1898-99

THE NEXT SESSION COMMENCES ON TUESDAY,

Complete Courses of Instruction are provided for the various Examinations in Arts and Science, and the Preliminary Scientific (M.B.) Examination of the University of London, for Students of Civil, Mechanical, and Electrical Engineering, and for those who desire to obtain acquaintance with some branch of Applied Science, including Chemistry, Metallurgy, &c. Students may, however, attend any Class or combination of Classes.

(There is also a Faculty of Medicine, a syllabus of which, containing full particulars, may be had gratis from Messrs. CORNISH, New Street.)
A SYLLABUS of the Arts and Science Faculties, with full information as to the various Lecture and Laboratory Courses, Lecture Days and Hours, Fees, Entrance and other Scholarships, Prizes, &c., may be had gratis from Messrs. CORNISH, New Street, Birmingham, or on application to the REGISTRAR, at the College.

UNIVERSITY COLLEGE, LONDON.

The Session of the Faculty of Medicine will commence on October 3 introductory Lecture, at 4 p.m., by Mr. SIMON SPENCER, Dental Surgeon to the Hospital.

The Examinations for the Entrance Exhibitions will commence on September 20. Scholarships, Exhibitions, and Prizes of the value of £800 are awarded annually.

In University College Hospital about 3000 In-patients and 35,000 Out-patients are treated during the year. Thirty-six Appointments, eighteen held resident (as House Surgeon, House Physician, Obstetric Assistant, &c.), are filled up by competition during the year, and these, as well as all Clerkships and Dressings, are open to Students of the Hospital without extra fee. Resident Officers receive free board and lodging. Prospectuses, and full information as to Classes, Prizes, &c., may be obtained from University College, Gower Street, W.C.

R J GODLEE, M.S., B.A., F.R.C.S., Dean.
J M. HORSBURGH, M.A., Secretary.

THE ELECTRICAL AND GENERAL ENGINEERING COLLEGE, AND EXPERIMENTAL ENGINEERING WORKS, 2 and 4 FENYVERN ROAD, EARL'S COURT, LONDON, S.W.,

Trains Students for Electrical, Mechanical and Mining Engineering. Develops Electrical and Mechanical Patents. Constructs Experimental and Special Machinery and Models to Specification.

THE LONDON HOSPITAL MEDICAL COLLEGE.

The WINTER SESSION commences on October 1. The Annual Dinner will be held in the College Library on Monday, October 3, Mr. MARSHALL-MOULLEN in the chair.

The Hospital is the largest in the kingdom; nearly 800 beds are in constant use, and no beds are closed. Being the only General Hospital for East London—i.e. for a million and a half people—the practice is immense. In patients last year, 11,146, Out-patients, 161,033, Accidents, 14,781; Major Operations, 1320.

APPOINTMENTS.—Owing to the enormous number of patients more Appointments, Salaried and Resident, are open to Students than at any other Hospital. Sixty of these qualified Appointments are made annually, and more than 150 Dressers, Clinical Clerks, &c., appointed every three months. All are free to Students of the College. Holders of Resident Appointments have Free Board.

SCHOLARSHIPS AND PRIZES.—Twenty-seven Scholarships and Prizes are given annually. FIVE ENTRANCE SCHOLARSHIPS will be offered in September.

Special Classes are held for the University of London and other higher Examinations. Special entries for Medical and Surgical Practice can be made. Qualified Practitioners will find excellent opportunities for studying the latest diseases.

A reduction of 15 Guineas is made to the Sons of Members of the Profession. ENLARGEMENT OF THE COLLEGE.—New Laboratories and Class-rooms for Bacteriology, Public Health, Operative Surgery, Chemistry, Biology, &c., will be completed by October 1.

The Clubs Union Athletic Ground is within easy reach of the Hospital. Luncheons and Dinners at moderate charges can be obtained in the Students' Club.

The Metropolitan and other Railways have Stations close to the Hospital and College.

For Prospectus and information as to Residence, &c., apply, personally or by letter, to

Mills End, E.

MUNRO SCOTT, Warden

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1898-99 will open on MONDAY October 5, when the prizes will be distributed at 3 p.m. by the Right Rev. the Lord Bishop of Rochester in the Governors' Hall.

Three Entrance Scholarships will be offered for competition in September, —One of £150 and one of £60 in Chemistry and Physics, with either Physiology, Botany, or Zoology, for first year's Students, one of £50 in Anatomy, Physiology, and Chemistry, for third year's Students, from the Universities.

Scholarships and money prizes of the value of £300 are awarded at the Seasonal Examinations, as well as several medals.

Special Classes are held throughout the year for the Preliminary Scientific and Intermediate M.B. Examinations of the University of London.

All Hospital Appointments are open to Students without charge.

A Rooms and an Athletic Ground are provided for Students.

The School Buildings and the Hospital can be seen on application to the Medical Secretary.

The fees may be paid in one sum or by instalments. Entries may be made separately to Lectures or to Hospital Practice, and Special Arrangements are made for Students entering from the Universities and for Qualified Practitioners.

A Register of approved Lodgings is kept by the Medical Secretary, who also has a List of Local Medical Practitioners, Clergymen, and others who receive Students into their houses.

For Prospectus and all particulars apply to Mr. RANDOLPH, the Medical Secretary.

H P HAWKINS, M.A., M.D. Oxon., Dean

HERIOT-WATT COLLEGE, EDINBURGH.

F GRANT OGILVIE, M.A., B.Sc., F.R.S.E., Principal.
DAY CLASSES—1898-99.

The Session extends from Tuesday, October 4, 1898, to Friday, June 9, 1899.

These Classes provide Courses of Study extending over one or more years, suitable for students who have previously completed the Curriculum of a Secondary School. The Principal Courses are—Physical and Chemical, Mechanical Engineering and Electrical Engineering. There are also Courses in French, German, Drawing, and Practices of Commerce. Class Fees, from £12 to £44 per Session Fee, £10 per year.

There is also a Preparatory Course of Instruction for Agricultural Students. Session Fee, £5 per year. An extract from the Calendar of the College, giving particulars of the Day Classes, and of the various Appliances, Laboratories, and Workshops available for instruction, may be had on application to the LIBRARIAN, at the College, or to the TREASURER of George Heriot's Trust.

DAVID LEWIS, Treasurer.

Treasurer's Chambers, 30 York Place, Edinburgh,
July 16, 1898.

CIVIL SERVICE COMMISSION. FORTHCOMING EXAMINATION.

Junior Assistant in the Science Branch of the South Kensington Museum (18-23), September 23.

The date specified is the latest at which Applications can be received. Forms or forms to be obtained, with particulars, from the SECRETARY, Civil Service Commission, London, S.W.

ELECTRICAL ENGINEERING.

The ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTION, 8 CHARING CROSS ROAD, LONDON
(Proprietors—Syndicate of Electrical Engineers, Ltd.)

The Rt. Hon the Earl of CRAWFORD, K.T., F.R.S., Chairman
The Rt. Hon Lord Castletown | Hugh Ezra Harrison
The Hon R. Brougham | Francis Ince
Robert Hammond | William G. Smith

Affords a Theoretical and Practical Training, and qualifies the Sons of Gentlemen for Appointments in Mechanical and Electrical Engineering after the Preliminary Training in Theory at the Institution. Students go through a Practical Course, first in the Mechanical Engineering Works and subsequently the Electrical Works, the Institution being associated with over 50 leading Firms and Engineers for this purpose. They are thus brought directly into association with prominent Companies and Firms, and secure an introduction to the Profession under the most favourable auspices. **APPOINTMENTS HAVE BEEN SECURED FOR OVER 80 PER CENT. OF THE STUDENTS** who have completed their Course since the foundation of the Institution, and applications continue to be received for competent men. Prospectus on application. The next Session commences on September 21.

HARTLEY COLLEGE, SOUTH-AMPTON.

SESSION 1898-99
PRINCIPAL—R. WALLACE STEWART, D.Sc. (Lon.)

The Day Classes of the College include the following Courses—
London University Courses in Arts and Science (Matriculation, Intermediate, and Final Courses in Arts and Science).
Science Courses for Medical Students and Dental Students.
Mechanical Engineering Course.
Electrical Engineering Course.

NEXT SESSION commences on SEPTEMBER 27, 1898.

Prospectures of above Courses may be obtained on application to the CLERK.

UNIVERSITY COLLEGE, NOTTINGHAM.

A LECTURER and DEMONSTRATOR in PHYSICS will be required in October. Salary, £450 to £480. Applications, which are to be sent in not later than August 24, should be made on forms supplied by the SECRETARY.

RESEARCH.—A well-appointed Chemical and Physical Laboratory can be used by those wishing to carry on Research. Open Day and Evening at any time convenient to Worker. Electric Lighting means (constant current) can be used for Electrical Experiments—Apply between 11 and 3 o'clock, or by letter, 9 Heathcote Street, Mecklenburgh Square, Gray's Inn Road.

CAMBRIDGE B.A. (First-class Honours), wants Situation as Analytical or Works Chemist. Good references—“W. E., Nassau Mills, Paterncroft, Lancashire.”

PHYSICAL DEMONSTRATOR (Camb. and Bonn), aged Twenty-two, desires Re-engagement. Experience in Coll. of Sc.—Address, “O. N., NATURE Office.”

EXAMINATIONS IN CHEMISTRY OR PHYSICS.—Students prepared for any Examination in Chemistry or Physics. Practical work in well-appointed Laboratory. Apply between 12 and 3 o'clock, or by letter, 9 Heathcote Street, Mecklenburgh Square, Gray's Inn Road.

QUERNMORE. LONDON BRANCH at 24 CHANCERY LANE, W.C.
Taught by JOHN GIBSON, M.A. (First Class, Camb.) and G. L. L. B.A. (First Class, London), for all Public Examinations. **Special Instruction in Scientific Agriculture** for successful practical Agriculture and Forestry in the British Islands or the Colonies, also in Geology, Botany, &c., Practical, Chemical, and Physical Laboratories. The “State Correspondent” and Higher Examination Journal gives up-to-date particulars of all the leading C.S. and other Examinations. Price 5d., post free. Price of One Guinea for competition each month, Special Prize of Five Guineas each June and December.

COSSOR X-RAY TUBES With Osmium and Iridium Anodes as supplied to J. Mackenzie Davidson, Esq.
ACTUAL MAKER,
67 FARRINGTON ROAD, E.C.
MERCURY PUMPS.

EXPERIMENTAL AND SCIENTIFIC GLASS-BLOWING.

**UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.**

TEMPORARY ASSISTANT LECTURER AND DEMONSTRATOR IN PHYSIOLOGY.

The Council is prepared to appoint for one year an Assistant Lecturer and Demonstrator in Physiology at a Salary of £120. Applications for this Post, together with testimonials, which need not be printed, to be sent to the undersigned on or before October 1, 1898.

J. AUSTIN JENKINS, B.A., Secretary and Registrar
University College, Cardiff,
August 12, 1898.

THE BRIDGES-LEE PHOTO-THEODOLITE

*The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.*

The Photo-Theodolite automatically records on the photograph all, or nearly all, the data necessary for the reduction of the photographs, including the Magnetic bearings,—thus considerably reducing the time spent and the risk of error in the interpretation of the photographs.

The Instrument is fitted with an Aluminium Body, 6-in. Azimuthal Circle, reading with Vernier to one minute of arc, 4-in. Compass, divided to half degrees. Telescope with erect and inverting Eyepieces, rapid Rectilinear Lens with Iris Diaphragm and Colour Screen, six double dark Slides in Mahogany Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description of the Instrument sent free on application.

CARD AND SLIP FILES.

Portion of Card File

The Ceres Card Files in Cabinets (with rod) for Library Catalogues, and in Boxes and Trays (without the rod) for other purposes, constitute the latest development of the Card System

The Bishop of Bristol:—"The convenience of the Writing Table with 'Ceres' Files is beyond words. So far as I can keep pace with my correspondence, there is never anxiety as to where a letter is, and the drawer with cards for notes of references, speeches, &c., makes me perpetually regret that I had not such a thing twenty years ago."

Sir H. H. Bamrose, M.P.:—"I am using the Card Box daily for a literary purpose, and I find it simply invaluable. As it lies on the table entries are made at the moment under their proper heads, and the facility of reference is such as no other mode of indexing I am aware of can touch."

For other varieties and sizes of Box Files, Cabinets, Writing Tables, Standing Desks, Card Files, &c., see Explanatory Pamphlet, Post Free

MACMILLAN & CO.'S BOOKS FOR HOLIDAY READING.

ALFRED LORD TENNYSON: a Memoir. By his SON. With Photogravure

Portraits 2 vols Medium 8vo. 36s net

MR. BODLEY'S FRANCE. In 2 vols. Demy 8vo. 21s. net.

EDINBURGH REVIEW.—"He has devoted himself to his task with great ability and the most praiseworthy industry. He has endeavoured to divest himself of English prejudice, and he writes in the character of an impartial and close observer of French political and social life for seven long years and as a devoted friend of the French people. Mr Bodley's book will be read by all men, and deserves to be read with care and discrimination."

A HISTORY OF THE INDIAN MUTINY, AND OF THE DISTURBANCES

WHICH ACCOMPANIED IT AMONG THE CIVIL POPULATION BY T RICE HOLMES Fifth Edition, revised
throughout and slightly enlarged With Maps and Plans. Extra Crown 8vo. 12s 6d
"T P" in the WEEKLY SUN says.—"It is but a poor and an insufficient compliment to say that the book is more interesting than any work of fiction. For myself I have read it as breathlessly as though it were an exciting novel; with that added sense that I was reading of reality and not of fiction. . . Impartiality, profound knowledge, a charming style, unassailable accuracy—these are qualities that are not often found in combination; they are found in this noteworthy volume."

HENRY OF GUISE AND OTHER PORTRAITS. By H. C. MACDOWALL. Extra
Crown 8vo 8s 6d net.

DAILY NEWS.—"The book is full of dramatic interest and may be confidently recommended to readers who have a taste for the romance of history."

LIFE AND LETTERS OF WILLIAM JOHN BUTLER, late Dean of Lincoln,
and sometime Vicar of Wantage. With Portraits. Demy 8vo. 12s 6d net.

LITERATURE.—"This biography is one of exceptional interest, and we trust that it will be widely and attentively studied."
HIGHWAYS AND BYWAYS IN DEVON AND CORNWALL. By ARTHUR H.

NORWAY. With Illustrations by JOSEPH PENNELL and HUGH THOMSON. Extra crown 8vo. 6s.

GUARDIAN.—"One of the prettiest and best books of the season."

BY THE RIGHT HON JAMES BRYCE, M.P.

IMPRESSIONS OF SOUTH AFRICA. By the Right Hon. JAMES BRYCE, M.P.,

Author of "The Holy Roman Empire," &c With Three Maps. Demy 8vo 14s. net.

THE TIMES.—"There are few who will not lay down the volume feeling that they know more than they ever expected or hoped to know upon the subject of which it treats."

SOUTH AFRICA OF TO-DAY. By Captain FRANCIS YOUNGHUSBAND, C.I.E.,
Indian Staff Corps, late Special Correspondent of *The Times* in South Africa, Author of "The Relief of Chitral." With
Illustrations. Demy 8vo. 8s. 6d. net.

SPECTATOR.—"Admirably fair and lucid. . . The sanest and most statesmanlike work that has yet appeared on the South African problem."

NEWMAN & GUARDIA, Ltd.,
90 & 92 Shaftesbury Avenue, London, W

JAS. J. HICKS, 8, 9 & 10 HATTON GARDEN, LONDON,

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special construction, and a simple and accurate arterial pressure gauge. It is marvellously sensitive, and consists of a metal tambour, the expansion of which is exhibited in a highly magnified form by means of an index or pointer which travels round a dial. This dial is graduated in millimetres of mercury. The armlet pump and pressure gauge, when not in use, fit conveniently into a leather case. By means of this instrument we believe that the arterial pressure can be taken in man as rapidly, simply, and accurately as the temperature can be taken with the clinical thermometer.

Price £5. Spare Bag and Tube, 5s.

The Instrument has a 5-in. Dial, and is packed in a
neat morocco Case with Handle
FULLER PARTICULARS ON APPLICATION.

OPPOSITE THE BRITISH MUSEUM.

Telegraphic Address: "TRUSLOVE, LONDON"

Proprietor—J. TRUSLOVE.

THE SCIENTIFIC MAN'S, NATURALIST'S, AND TRAVELLER'S CAMERA

IS THE

Stereoscopic Company's BINOCULAR,

Because when ready to take 12 Pictures it weighs 19 ounces only.

It is used like a Field Glass. Takes instantaneous and time exposures. Gives Pictures 7 in. by 5 in. when used with the simple printing and enlarging apparatus. Price £5 5s. only. Complete with enlarging apparatus, £10 10s. FREE Lessons to Purchasers.

From R. BOWDLER SHARPE, Esq., LL.D., Assistant Keeper, Zoological Department, British Museum.

"I have received the remainder of the proofs of my photographs, and I must say that I am delighted with them. I consider it one of the best day's work I ever did when I bought one of your 'Binocular' Cameras. The ease with which it is worked, and the excellent results obtained, make it a most pleasurable accompaniment of a summer's outing, and, in my case, 90 per cent. of my Norway photographs have come out beautifully, while even the small remainder cannot be considered failures. I think this is a grand result, when you remember that I had little or no experience of photography, and had only time for an hour's instruction in your rooms the day before I sailed, and, further, that I had to make my own dark rooms in Norway in the best way I could. I am looking forward to having much pleasure this summer from the faithful 'Binocular,' and I have recommended it to all my friends."

CATALOGUES FREE.

Printed by RICHARD CLAY AND SONS, LIMITED, at 2 & 3 Strand Street Hill, Queen Victoria Street, in the City of London, and published by MACMILLAN & CO., LIMITED, at St. Martin's Street, London, W.C., and THE MACMILLAN COMPANY, 66 Fifth Avenue, New York.—TRUSLOVE, August 18, 1898.

MACMILLAN & CO.'S BOOKS FOR STUDENTS OF ZOOLOGY.

A TEXT-BOOK OF ZOOLOGY. By T. JEFFERY PARKER, D.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, N.Z., and WILLIAM A. HASWELL, M.A., D.Sc., F.R.S., Professor of Biology in the University of Sydney, N.S.W. In Two Vols. With Illustrations. Medium 8vo, 36s net.

LITERATURE—"The scheme of classification is on the whole so good that even those who find fault with matters of detail will admit its general excellence. The sections on Distribution—geographical, bathymetrical, and geological—and on The Philosophy of Zoology have been written with extreme care, the latter especially being full of pregnant remarks and suggestions. A useful chapter on the History of Zoology is appended, from which a true idea of the perspective of things can be gathered. Both volumes are copiously indexed, and reference to any heading is thus made easy."

A TEXT-BOOK OF ENTOMOLOGY, including the Anatomy, Physiology, Embryology and Metamorphoses of Insects, for use in Agricultural and Technical Schools and Colleges, as well as by the working Entomologist. By ALPHIUS S. PACKARD, M.D., Ph.D., Professor of Zoology and Geology, Brown University. Medium 8vo, 18s net.

LITERATURE—"Dr A. S. Packard has attempted no easy task, but his thirty years' study of the huge class of insects qualifies him to accomplish it, and he is to be congratulated on his work."

ESSAYS ON MUSEUMS AND OTHER SUBJECTS CONNECTED WITH NATURAL HISTORY. By Sir WILLIAM HENRY FLOWER, K.C.B., D.C.L., D.Sc., LL.D., Ph.D., F.R.S., F.R.C.S., F.Z.S., Correspondent of the Institute of France, &c. Demy 8vo, 12s net.

ATHENÆUM—"Many of the essays possess permanent value, and all were well worthy of being printed afresh."

A TEXT-BOOK OF COMPARATIVE ANATOMY. By Dr ARNOLD LANG, Professor of Zoology in the University of Zürich. With Preface to the English Translation by Dr ERNEST HAECKEL. Translated by HENRY M. BERNARD, M.A. Cantab., and MATTHIAS BERNARD. Vols I and II (comprising the Invertebrates). 8vo. 17s net each.

LESSONS IN ELEMENTARY ANATOMY. By ST. GEORGE MIVART, F.R.S., Author of "The Genesis of Species." Fcap 8vo. 6s 6d.

ELEMENTS OF THE COMPARATIVE ANATOMY OF VERTEBRATES. Adapted from the German of ROBERT WIDDERHIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Freiburg, in Baden. By W. NEWTON PARKER, Professor of Biology in the University College of South Wales and Monmouthshire. With additions by the Author and Translator. 270 Woodcuts. Medium 8vo. Second Edition. 12s 6d net.

The STRUCTURE OF MAN. An INDEX to his PAST HISTORY. By ROBERT WIDDERHIM. Translated by H. and M. BERNARD. The Translation, Edited and Annotated, and a Preface written by G. B. HOWES, F.R.S., Professor of Zoology, Royal College of Science, London. With 105 Figures in the Text. 8vo. 8s net.

A COURSE OF INSTRUCTION in ZOOLOGY. Vertebrata. By T. JEFFERY PARKER, F.R.S., Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo. 8s 6d.

An INTRODUCTION to the OSTEOLOGY OF THE MAMMALIA. By Sir WILLIAM HENRY FLOWER, F.R.S., F.R.C.S., Director of the Natural History Department of the British Museum. Illustrated. Third Edition. Revised with the assistance of HANS GADOW, Ph.D., Lecturer on the Advanced Morphology of Vertebrates in the University of Cambridge. Crown 8vo. 10s 6d.

A TREATISE ON COMPARATIVE EMBRYOLOGY. By the late Prof F. M. BALFOUR, M.A., F.R.S. In two Vols. Second Edition. Medium 8vo. Vol I 18s. Vol II 21s.

The ELEMENTS of EMBRYOLOGY. By Prof MICHAEL FOSTER, M.D., F.R.S., and the late Prof F. M. BALFOUR, F.R.S. Second Edition, revised. Edited by A. SPEDDING, M.A., and W. HEAPP, M.A. Illustrated. Crown 8vo. 10s 6d.

STRUCTURE AND LIFE of BIRDS. By F. W. HEADLEY, Assistant Master at Haikbury College. Illustrated. Crown 8vo. 7s 6d.

The NATURAL HISTORY of the MARKETABLE MARINE FISHERIES of the BRITISH ISLANDS. By J. T. CUNNINGHAM, M.A. With Preface by E. RAY LANKESTER, F.R.S. Illustrated. Medium 8vo. 7s 6d net.

NATURAL HISTORY of AQUATIC INSECTS. By I. C. MIALL, F.R.S., Professor of Biology in the Yorkshire College, Leeds. Illustrated. Crown 8vo. 6s.

THE ORIGIN AND METAMORPHOSES OF INSECTS. By Sir JOHN LUBBOCK, F.R.S. With Illustrations. 3s 6d. [*Nature Series*].

MONOGRAPH of the BRITISH CICADÆ or TETTIGONIDÆ (Froghoppers and Grasshoppers). By GEORGE BOWDLER BUCKTON, F.R.S., Illustrated by more than 400 Coloured Drawings. Two Vols. Demy 8vo. 33s 6d each, net. Also in Eight Parts. 8s each, net.

A HANDBOOK OF BRITISH LEPIDOPTERA. By EDWARD MEYRICK, B.A., F.Z.S., F.E.S., Assistant Master at Marlborough College. Extra Crown 8vo. 10s. 6d net.

THE CAMBRIDGE NATURAL HISTORY.

Edited by S. F. HARMER, M.A., Fellow of King's College, Cambridge, Superintendent of the University Museum of Zoology, and A. E. SHIPLEY, M.A., Fellow of Christ's College, Cambridge, University Lecturer on the Morphology of Invertebrates.

To be completed in Ten Volumes. 8vo. Price 17s. net each.

Intended in all respects to be a Standard Natural History accurate enough to be of use to the Student, and at the same time popular enough for the general reader who desires trustworthy information as to the structure and habits of all members of the Animal Kingdom, from the Protozoa to the Mammals. The Volumes are fully illustrated by original figures drawn where possible from nature. When complete the Series is one which should be indispensable in all Libraries, whether public or private.

NOW READY

WORMS, LEECHES, etc.

VOLUME II

FLATWORMS. By F. W. GAMBLE, M.Sc. Vict. Owens College

NEMERTINES. By Miss L. SHELDON, Newnham College, Cambridge

THREAD-WORMS, &c. By A. E. SHIPLEY, M.A., Fellow of Christ's College, Cambridge

ROTIFERS. By MARCUS HARTOG, M.A. Trinity College, Cambridge, D.Sc. Lond., Professor of Natural History in the Queen's College, Cork.

POLYCHAET WORMS. By W. BLAXLAND BENHAM, D.Sc. Lond., Hon. M.A. Oxon., Aldrichian Demonstrator of Comparative Anatomy in the University of Oxford

EARTHWORMS AND LEECHES. By F. E. BIDDARD, M.A. Oxon., F.R.S., Prosector to the Zoological Society, London

GEPHYREA, &c. By A. E. SHIPLEY, M.A., Fellow of Christ's College, Cambridge

POLYZOA. By S. F. HARMER, M.A., Fellow of King's College, Cambridge

ACADEMY—"Of the importance of the new volume of the Cambridge Natural History there can be no doubt. It may be safely said that the information contained in it has never before been collected into one book, English or foreign, and all students of zoology will be grateful to the promoters of the Cambridge series for a treatise which will save them many a journey to the libraries and much weary searching in periodicals for a long time to come this book will remain the best text book on the subject."

NATURE—"Taken as a whole the book is fully worthy of its place in this attractive series."

NATURAL SCIENCE—"Certain to prove a most welcome addition to English zoological literature. The whole is admirably illustrated. The index, to crown all, is a thoroughly good and full one."

CAMBRIDGE REVIEW—"We may say with confidence that the same amount of information, within the same compass, is to be had in no other zoological work."

SHELLS.

VOLUME III

MOLLUSCS AND BRACHIOPODS. By the Rev. A. H. COOKE, M.A., A. E. SHIPLEY, M.A., and F. R. C. REED, M.A.

TIMES—"There are very many, not only among educated people who take an interest in science, but even among specialists, who will welcome a work of reasonable compass and handy form containing a trustworthy treatment of the various departments of Natural History by men who are familiar with, and competent to deal with, the latest results of scientific research. Altogether, to judge from this first volume, the Cambridge Natural History promises to fulfil all the expectations that its prospectus holds out."

FIELD—"We know of no book available to the general reader which affords such a vast fund of information on the structure and habits of molluscs."

KNOWLEDGE—"If succeeding volumes are like this one, the Cambridge Natural History will rank as one of the finest works on natural history ever published."

WESTMINSTER REVIEW—"Should find a place in the library of every naturalist."

INSECTS AND CENTIPEDES.

VOLUME V

PERIPATUS. By ADAM SEDGWICK, M.A., F.R.S. MYRIAPODS. By F. G. SINCLAIR, M.A. INSECTS. Part I. By DAVID SHARP, M.A. Cantab., M.B. Edin., F.R.S.

FIELD—"Although written for the student and the specialist, the book is not the less adapted to all intelligent readers who wish to make themselves thoroughly acquainted with the habits, structure, and the modern classification of the animals of which it treats. To such it cannot be recommended too strongly."

ATHENÆUM—"This book will find a place in the library of most entomologists, prove a welcome boon to weak brethren who are compelled to lecture—*dicenda distantibus*—and occupy by the side of Westwood's 'Modern Classification' and Börner's 'Manual' a niche that has long been empty."

Prof. RAPHAEL MELDOLA, F.R.S., F.C.S., in his *Presidential Address to the Entomological Society of London*, said—"The authors of this volume are certainly to be congratulated upon having furnished such a valuable contribution to our literature. When its successor appears, and I will venture to express the hope that this will be at no very distant period, we shall be in possession of a treatise on the natural history of insects which, from the point of view of the general reader, will compare most favourably with any similar work that has been published in the English language."

BIRDS.

VOLUME IX

By A. H. EVANS

[Ready shortly.]

** The next Volume to appear will be the completion of Dr. SHARP's admirable treatise on INSECTS. This may be looked for not later than January.

BROWNING'S PLATYSCOPIC LENS. With Larger Angles, Increased Field, and Improved Definition

A scientific
AN ACHROMATIC COMBINATION,
COMBINING THE DEFINITION OF A MICROSCOPE WITH THE
PORTABILITY OF A LOCKET LENS

If you carry a small Platyscopic or Pocket Lens (which every observer of Nature ought to do) —GRANT ALLEN in *Annals of Science* writes:—
"The Platyscopic Lens is invaluable to botanists, mineralogists or anyone of glass as it focuses about three times as far from the object as the Goldington Lens. It allows opaque objects to be examined easily."
The Platyscopic Lens is made of four degrees of power, magnifying respectively to 15, 20, 25 and 30 diameters, the lowest power having the largest field, is the best adapted for general use.

The Lenses are set in Ebony Cells and mounted in Tortoiseshell Frames.
Price of the Platyscopic Lens, mounted in Tortoiseshell, magnifying either 10, 15, 20, or 30 diameters, 18s. 6d. each power.

68 CORNHILL,
LONDON.

QUEEN'S COLLEGE, GALWAY.

SESSION 1898-99.

MATRICULATION EXAMINATION, 21st OCTOBER, 1898.

The Matriculation Certificates of the Queen's Colleges Belfast and Cork, and of the Royal University of Ireland, and of other Universities within the United Kingdom, are accepted by this College. All Scholarships and Prizes are open to Women.

JUNIOR SCHOLARSHIPS.

FACULTY OF ARTS.

First Year—Five Literary and Five Science, value £25 each.
Second Year—Five Literary and Five Science, value £25 each.
Third Year—Five Literary and Five Science, value £25 each.
The Examination for Scholarships of the First Year will commence on the 24th OCTOBER, of the Second and Third Years, on the 20th OCTOBER.

FACULTY OF LAW

First Year—One, value £25.
Second Year—One, value £25.
The Examinations will commence on the 16th DECEMBER.

FACULTY OF MEDICINE

Two of the First Year, Two of the Second Year, Two of the Third Year, and Two of the Fourth Year, value £25 each.
Scholarships of the Second, Third, and Fourth Years may be competed for by Students who have attained the requisite standing in any Medical School recognised by the College Council, and have Matriculated in this College.

The Examinations for Scholarships of the First Year will commence on the 16th OCTOBER, of the Second Year, on the 22nd OCTOBER, of the Third and Fourth Years, on the 29th OCTOBER.
Clinical Instruction is given at the Galway General Hospital, the Galway Union Hospital, the Galway Fever Hospital, and in Vaccination at the Galway Dispensary.

Lectures can be attended by Women.

DEPARTMENT OF ENGINEERING

First Year—Two, value £20 each.
Second Year—Two, value £20 each.
Third Year—One, value £20.

The Examinations for Scholarships of the First Year will commence on the 16th OCTOBER, of the Second Year, on the 22nd OCTOBER, of the Third Year, on the 29th OCTOBER.
All the above Scholarships (in Arts, Law, Medicine, and Engineering) are tenable for One Year, and Candidates must have Matriculated in this College.

EXAMINATIONS

The Council may award Exhibitions, tenable for One Year, to Matriculated Students at the Queen's College, Galway.
Information as to Fees, and Copies of the Prospectus, may be had on application to the REGISTRAR.

By Order of the Deputy President,

EDWARD TOWNSEND

11th August, 1898.

REGISTRAR

HERIOT-WATT COLLEGE, EDINBURGH.

F. GRANT OGILVIE, M.A., B.Sc., F.R.S.E., Principal.
DAY CLASSES—SESSION 1898-99.

The Session extends from Tuesday, October 4, 1898, to Friday, June 5, 1899.

These Classes provide Courses of Study extending over one or more years, suitable for Students who have previously passed through the Curriculum of a Secondary School. The principal Courses are—Physical and Chemical, Mechanical Engineering and Electrical Engineering. There are also Classes in French, German, Drawing, and Practice of Commerce Class Fees, from £1 1s to £4 1s per Session. Fees, £50 to £100.

There is also a Preparatory Course of Instruction for Agricultural Students. Session Fee, £3 3s. An extract from the Calendar of the College, giving particulars of the Day Classes and of the various Appointments, Laboratories, and Workshops available for instruction, may be had on application to the REGISTRAR, at the College, or to the TREASURER of George Heriot's Trust.

DAVID LEWIS, Treasurer

Treasurer's Chambers, 30 York Place, Edinburgh,
July 18, 1898.

VICTORIA UNIVERSITY.

THE YORKSHIRE COLLEGE, LEEDS.

The 56th Session of the Department of Science, Technology, and Arts will begin on October 11, and the 56th Session of the School of Medicine on October 3, 1898.

The Classes prepare for the following Professions: Chemistry, Civil, Mechanical, Electrical, and Sanitary Engineering, Mining, Textile Industries, Dyeing, Leather Manufacture, Agriculture, School Teaching, Medicine, and Surgery.

University Degrees are conferred in the Faculties of Arts, Science, Medicine, and Surgery.

London Hospitals have been established for Students' residence.
Prospectus of any of the above may be had from the REGISTRAR.

ENGINEERING AND CHEMISTRY.

CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Instruction at the Institute's CENTRAL TECHNICAL COLLEGE (Exhibition Road) are for Students not under 16 years of age, those at the Institute's TECHNICAL COLLEGE, FINCHLEY, are of an Intermediate Grade for Students not under 14 years of age. The Entrance Examinations to both Colleges are held in September, and the Sessions commence in October. Particulars of the Entrance Examinations, Scholarships, Fees, and Courses of Study, may be obtained from the respective Colleges, or from the Head Office of the Institute, Gresham College, Basinghall Street, E.C.

CITY AND GUILDS CENTRAL TECHNICAL COLLEGE.

(EXHIBITION ROAD, S.W.)

A College for higher Technical Instruction for Students not under 16 years of age, to become Civil, Mechanical or Electrical Engineers, Chemical and other Manufacturers, and Teachers. Fees for a full Associateship Course, £25 per Session. Professors—

Civil and Mechanical Engineering W. C. UNWIN, F.R.S., M. Inst. C.E.
Physics and Electrical Engineering W. G. PEARSON, F.R.S., F.Inst. Phys.
Chemistry H. E. ARMSTRONG, Ph.D., LL.D.
Mechanics and Mathematics O. HENRICI, Ph.D., LL.D., F.R.S.

CITY AND GUILDS TECHNICAL COLLEGE, FINCHLEY.

(LEONARD STREET, CITY ROAD, E.C.)

Provides Courses of Intermediate Instruction for Day Students not under 14 years of age, preparing to enter Engineering and Chemical Industries. Fees, £15 per Session. Professors—

Physics and Electrical Engineering S. P. THOMPSON, D.Sc., F.R.S.
Mechanical Engineering W. E. DALRY, M.A., B.Sc., M.I.M.E.
Mathematics R. MELDOLA, F.R.S., F.I.C.
Chemistry JOHN WATNEY, Hon. Secretary

City and Guilds of London Institute,
Gresham College, Basinghall Street, E.C.

GUY'S HOSPITAL MEDICAL SCHOOL.

The WINTER SESSION will begin on MONDAY, OCTOBER 3. Entrance Scholarships of the combined value of £400 are awarded annually, and numerous Prizes and Medals are open for Competition by Students of the School.

The number of Patients treated in the Wards during last year exceeded 6000.

Hospital Appointments are made strictly in accordance with the merits of the Candidates, and without extra payment. There are 18 Resident Appointments open to Students of the Hospital annually without payment of additional fees, and numerous Non-resident Appointments in the General and Special Departments. The Queen Victoria Ward, recently re-opened, will provide additional accommodation for Gynaecological and Maternity Cases.

The College accommodates 60 students, under the supervision of a Resident Warden.
The Dental School provides the full Curriculum required for the L.D.S. England.

The Clubs Union Athletic Ground is easily accessible.
A Handbook of Information for those about to enter the Medical Profession will be forwarded on application.

For the Prospectus of the School, containing full particulars as to Fees, Course of Study, Regulations of the College, &c., apply, personally or by letter, to the DEAN, Guy's Hospital, London Bridge, S.E.

GUY'S HOSPITAL.

ENTRANCE SCHOLARSHIPS, to be competed for in September, 1898.

TWO OPEN SCHOLARSHIPS in ARTS, one of the value of £100, open to Candidates under 20 years of age, and one of £50, open to Candidates under 18 years of age.

TWO OPEN SCHOLARSHIPS in SCIENCE, one of the value of £100, and another of £50, open to Candidates under 25 years of age.

ONE OPEN SCHOLARSHIP for University Students who have completed their study of Anatomy and Physiology, of the value of £50.

Full particulars may be obtained on application to the DEAN, Guy's Hospital, London Bridge, S.E.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.

PRELIMINARY SCIENTIFIC CLASS.

Systematic Courses of Lectures and Laboratory Work in the subjects of the Preliminary Scientific and Intermediate B.Sc. Examinations of the University of London will commence on October 3, and continue till July, 1899.

Fee for the whole Course, £20, or £10 able to Students of the Hospital; or single subjects may be taken.

There is a Special Class for the January Examination.

For further particulars apply to the Warden of the College, St. Bartholomew's Hospital, London, E.C.

A Handbook forwarded on application.

BRITISH MUSEUM.

The Reading Rooms will be closed from Thursday, September 1, to Monday, September 5, inclusive.

E MAUND THOMPSON,
Director and Principal Librarian

British Museum, August 25, 1898.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

The Winter Session, 1898-99, will commence on Monday, October 3. Dr. ARTHUR F. VOZVACKA will deliver an Introductory Address, after which the Prizes gained during the previous year will be distributed. Two Entrance Scholarships (value £100 and £60) will be open for Competition on September 25 and 27.

One Entrance Scholarship (value £60), open to Students of the University of Cambridge who have passed the Second M.B. Exam. and of the University of Oxford who have passed the First M.B. Exam. will be competed for on September 22 and 23.

Besides Scholarships and Prizes, there are annually Eighteen Resident Hospital Appointments open to Students, without extra fee.

The Composition Fee for general Students for the whole Medical Curriculum is 120 Guineas. Special provision is made for Dental Students and for Candidates for the Preliminary Scientific (M.B.) Examination.

Special Terms are made in favour of University Students who have already commenced their Medical Studies, and of University of London Students who have passed the Preliminary Scientific Examination.

The New School Buildings, which provide new and fully equipped Laboratories for Physiology, Pathology, and Bacteriology, as well as a new Dissecting Room and Chemical Theatre and Laboratory, will be opened next Session.

The Residential College adjoins the Hospital, and provides accommodation for Thirty Students.

Prospectuses and all Particulars may be obtained from

W. PASTEUR, M.D., Dean

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE

TEMPORARY ASSISTANT LECTURER AND DEMONSTRATOR IN PHYSIOLOGY

The Council is prepared in appointment for one year as Assistant Lecturer and Demonstrator in Physiology at a Salary of £1200.

Applications for this Post, together with testimonials, which need not be printed, to be sent to the undersigned on or before October 1, 1898.

J. AUSTIN JENKINS, B.A., Secretary and Registrar
University College Cardiff,
August 11, 1898.

HARTLEY COLLEGE, SOUTHAMPTON.

Applications are invited for the Post of ASSISTANT LECTURER and DEMONSTRATOR IN PHYSICS and ELECTRICAL ENGINEERING.

A special knowledge of Experimental Physics or of Electrical Engineering, but not of both, is required.

Salary, £1200 per annum.

Applications must be received on or before Saturday, September 17, 1898.

Particulars may be obtained on application to the CLERK.

WANTED.—CHIEF CHEMIST and

MANAGER OF WORKS, by a leading London Firm of Manufacturing Chemists employing several hundred people. The qualifications necessary for the position are high and well grounded scientific knowledge and attainments, good practical experience in carrying out manufacturing processes, exceptional powers of organisation and administration, tact, good judgment, capability to direct and control scientific workers engaged in the manufacture of fine medicinal chemicals and pharmaceutical products. A gentleman with University training and Degrees preferred. The position commands a liberal salary. Replies will be treated in the strictest confidence if so desired.—Address, stating age, qualifications, and experience, to "Manager," c/o Messrs. MARKS, STEWART, & Co., 37 Coleman Street, London.

THE YORKSHIRE COLLEGE, LEEDS.

AN ASSISTANT LECTURER and DEMONSTRATOR IN PHYSICS will be required at the beginning of next Session.

Applications will be received up to September 3 by the REGISTRAR of the College, from whom further particulars may be obtained.

BATTERSEA POLYTECHNIC, S.W.

The Governing Body require the Services of a LABORATORY STEWARD and LECTURE ASSISTANT in the CHEMICAL DEPARTMENT.

For particulars send stamped addressed envelope at once to the SECRETARY.

SCIENTIFIC ASSISTANT, with view to

Partnership, Wanted by Consulting Engineer in good practice. Write, with full particulars of training and qualifications, to "Dynamo," c/o Strachan & Co., 495 Strand.

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.

The Photo Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduc-
tion of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs

The instrument is fitted with
an Aluminium Body, 6-in.
Azimuthal Circle, reading with
Vernier to one minute of arc,
4 in. Compass, divided to half
degrees. Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, **£45.**

THE CAMBRIDGE NATURAL HISTORY.

Edited by S. F. HARMER, M.A., Fellow of King's College, Cambridge, Superintendent of the University Museum of Zoology, and A. E. SHIPLEY, M.A., Fellow of Christ's College, Cambridge, University Lecturer on the Morphology of Invertebrates

To be completed in Ten Volumes. 8vo. Price 17s. net each:

Intended in all respects to be a Standard Natural History accurate enough to be of use to the Student, and at the same time popular enough for the general reader who desires trustworthy information as to the structure and habits of all members of the Animal Kingdom, from the Protozoa to the Mammals. The Volumes are fully illustrated by original figures drawn where possible from nature. When complete the Series is one which should be indispensable in all Libraries, whether public or private.

NOW READY

WORMS, LEECHES, etc.

VOLUME II

- FLATWORMS By F. W. GAMBLE, M.Sc. Vict., Owens College
NEMERTINES By Miss L. SHELDON, Newnham College, Cambridge
THREAD-WORMS, &c. By A. E. SHIPLEY, M.A., Fellow of Christ's College, Cambridge
ROTIFERS By MARCUS HARTOG, M.A. Trinity College, Cambridge, D.Sc. Lond., Professor of Natural History in the Queen's College, Cork
POLYCHAET WORMS By W. BLAXLAND BENHAM, D.Sc. Lond., Hon. M.A. Oxon., Aldrichian Demonstrator of Comparative Anatomy in the University of Oxford
EARTH-WORMS AND LEECHES By F. E. BLUNNARD, M.A. Oxon., F.R.S., Professor to the Zoological Society, London
GEPHYRÆA, &c. By A. E. SHIPLEY, M.A., Fellow of Christ's College, Cambridge
POLYZOA By S. F. HARMER, M.A., Fellow of King's College, Cambridge

ACADEMY—"Of the importance of the new volume of the Cambridge Natural History there can be no doubt. It may be safely said that the information contained in it has never before been collected into one book, English or foreign; and all students of zoology will be grateful to the promoters of the Cambridge series for a treatise which will save them many a journey to the libraries and much weary searching in periodicals. For a long time to come this book will remain the best text-book on the subject."

NATURE—"Taken as a whole the book is fully worthy of its place in this attractive series."

NATURAL SCIENCE—"Certain to prove a most welcome addition to English zoological literature. The whole is admirably illustrated. The index, to crown all, is a thoroughly good and full one."

CAMBRIDGE REVIEW—"We may say with confidence that the same amount of information, within the same compass, is to be had in no other zoological work."

SHELLS.

VOLUME III

- MOLLUSCS AND BRACHIOPODS By the Rev A. H. COOKE, M.A., A. E. SHIPLEY, M.A., and F. R. C. REED, M.A.

TIMES—"There are very many, not only among educated people who take an interest in science, but even among specialists, who will welcome a work of reasonable compass and handy form containing a trustworthy treatment of the various departments of Natural History by men who are familiar with, and competent to deal with, the latest results of scientific research. Altogether, to judge from this first volume, the Cambridge Natural History promises to fulfil all the expectations that its prospectus holds out."

FIELD—"We know of no book available to the general reader which affords such a vast fund of information on the structure and habits of molluscs."

KNOWLEDGE—"If succeeding volumes are like this one, the Cambridge Natural History will rank as one of the finest works on natural history ever published."

WESTMINSTER REVIEW—"Should find a place in the library of every naturalist."

INSECTS AND CENTIPEDES.

VOLUME V

- PERIPATUS By ADAM SEDGWICK, M.A., F.R.S. MYRIAPODS By F. G. SINCLAIR, M.A.
INSECTS. Part I By DAVID SHARP, M.A. Cantab., M.B. Edin., F.R.S.

FIELD—"Although written for the student and the specialist, the book is not the less adapted to all intelligent readers who wish to make themselves thoroughly acquainted with the habits, structure, and the modern classification of the animals of which it treats. To such it cannot be recommended too strongly."

ATHENÆUM—"This book will find a place in the library of most entomologists, prove a welcome boon to weak brethren who are compelled to lecture—*doendo discimus*—and occupy by the side of Westwood's 'Modern Classification' and Burmeister's 'Manual' a niche that has long been empty."

Prof. RAPHAEL MELDOLA, F.R.S., F.C.S., in his Presidential Address to the Entomological Society of London, said—"The authors of this volume are certainly to be congratulated upon having furnished such a valuable contribution to our literature. When its successor appears, and I will venture to express the hope that this will be at no very distant period, we shall be in possession of a treatise on the natural history of insects which, from the point of view of the general reader, will compare most favourably with any similar work that has been published in the English language."

BIRDS.

MACMILLAN & CO'S BOOKS FOR STUDENTS OF ZOOLOGY.

A TEXT-BOOK OF ZOOLOGY. By T. JEFFERY PARKER, D.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, N.Z., and WILLIAM A. HASWELL, M.A., D.Sc., F.R.S., Professor of Biology in the University of Sydney, N.S.W. In Two Vols. With Illustrations. Medium 8vo, 36s net.

LITERATURE—"The scheme of classification is on the whole so good that even those who find fault with matters of detail will admit its general excellence. The sections on Distribution—geographical, bathymetrical, and geological—and on The Philosophy of Zoology have been written with extreme care, the latter especially being full of pregnant remarks and suggestions. A useful chapter on the History of Zoology is appended, from which a true idea of the perspective of things can be gathered. Both volumes are copiously indexed, and reference to any heading is thus made easy."

A TEXT-BOOK OF ENTOMOLOGY, including the Anatomy, Physiology, Embryology and Metamorphoses of Insects, for use in Agricultural and Technical Schools and Colleges, as well as by the working Entomologist. By ALPHEUS S. PACKARD, M.D., Ph.D., Professor of Zoology and Geology, Brown University. Medium 8vo, 18s net.

LITERATURE—"Dr A. S. Packard has attempted no easy task, but his thirty years' study of the huge class of insects qualifies him to accomplish it, and he is to be congratulated on his work."

ESSAYS ON MUSEUMS AND OTHER SUBJECTS CONNECTED WITH NATURAL HISTORY. By Sir WILLIAM HENRY FLOWER, K.C.B., D.C.L., LL.D., Ph.D., F.R.S., F.R.C.S., P.Z.S., Correspondent of the Institute of France, &c. Demy 8vo, 12s net.

ATHENÆUM—"Many of the essays possess permanent value, and all were well worthy of being printed afresh."

A TEXT-BOOK OF COMPARATIVE ANATOMY. By Dr ARNOLD LANG, Professor of Zoology in the University of Zürich. With Preface to the English Translation by Dr ERNST HAECKEL. Translated by HENRY M. BERNARD, M.A. Cantab., and MARILDA BERNARD. Vols. I. and II. (completing the Invertebrates). 8vo 17s net each.

LESSONS IN ELEMENTARY ANATOMY. By ST. GEORGE MIVART, F.R.S., Author of "The Genesis of Species." Fcap 8vo 6s 6d.

ELEMENTS of the COMPARATIVE ANATOMY of VERTEBRATES. Adapted from the German of ROBERT WIEDERSHEIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Freiburg, in Baden. By W. NEWTON PARKER, Professor of Biology in the University College of South Wales and Monmouthshire. With additions by the Author and Translator. 270 Woodcuts. Medium 8vo. Second Edition. 12s 6d net.

THE STRUCTURE of MAN: An INDEX to his PAST HISTORY. By ROBERT WIEDERSHEIM. Translated by H. and M. BERNARD. The Translation, Edited and Annotated, and a Preface written by G. B. HOWES, F.R.S., Professor of Zoology, Royal College of Science, London. With 105 Figures in the Text. 8vo 8s net.

A COURSE of INSTRUCTION in ZOOLOGY. Vertebrata. By T. JEFFERY PARKER, F.R.S., Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo. 8s 6d.

AN INTRODUCTION to the OSTEOLOGY of the MAMMALIA. By Sir WILLIAM HENRY FLOWER, F.R.S., F.R.C.S., Director of the Natural History Department of the British Museum. Illustrated. Third Edition. Revised with the assistance of HANS GADOW, Ph.D., Lecturer on the Advanced Morphology of Vertebrates in the University of Cambridge. Crown 8vo. 10s 6d.

A TREATISE on COMPARATIVE EMBRYOLOGY. By the late Prof F. M. BALFOUR, M.A., F.R.S. In two Vols. Second Edition. Medium 8vo. Vol. I 18s. Vol. II 21s.

The ELEMENTS of EMBRYOLOGY. By Prof MICHAEL POSTER, M.D., F.R.S., and the late Prof F. M. BALFOUR, F.R.S. Second Edition, revised. Edited by A. SHIGWICK, M.A., and W. HEAPE, M.A. Illustrated. Crown 8vo 10s 6d.

STRUCTURE and LIFE of BIRDS. By F. W. HEADLEY, Assistant Master at Haileybury College. Illustrated. Crown 8vo 7s 6d.

The NATURAL HISTORY of the MARKETABLE MARINE FISHES of the BRITISH ISLANDS. By J. T. CUNNINGHAM, M.A. With Preface by E. RAY LANKESTER, F.R.S. Illustrated. Medium 8vo 7s 6d net.

NATURAL HISTORY of AQUATIC INSECTS. By L. C. MIALL, F.R.S., Professor of Biology in the Yorkshire College, Leeds. Illustrated. Crown 8vo 6s.

THE ORIGIN and METAMORPHOSES of INSECTS. By Sir JOHN LUBBOCK, F.R.S. With Illustrations. 3s. 6d. [Nature Series]

MONOGRAPH of the BRITISH CICADE or TETTIGIDE (Froghoppers and Grasshoppers). By GEORGE BOWDLER BUCKTON, F.R.S. Illustrated by more than 400 Coloured Drawings. Two Vols. Demy 8vo. 33s 6d each, net. Also in Eight Parts. 8s each, net.

A HANDBOOK of BRITISH LEPIDOPTERA. By EDWARD MEYRICK, B.A., F.Z.S., F.E.S., Assistant Master at Marlborough College. Extra Crown 8vo 10s. 6d net.

THE NEW STIGMATIC LENS.

SERIES II P/6

BRITISH DESIGN AND WORKMANSHIP.

Is the best All round Lens for either Professional or Amateur use

Each lens will give perfect definition with full aperture to the extreme corners of the plate
it is sold to cover with smaller stops it will cover at least two sizes larger giving perfect sharp-
ness all over the plate and thus becoming a wide angle lens of the highest excellence. Either
combination may be used separately giving foci of about 1 1/2 and 2 times the length of that of
the lens when used intact. The advantage of thus being able to choose the best point of view,
irrespective of distance, will be at once apparent to the artistic worker

EQUIVALENT TO FOUR LENSES AT THE PRICE OF ONE

Eleven Sizes are now ready from 3 1/2 to 18 inches eq. focus

BALLIOL COLLEGE, CHRIST CHURCH, AND TRINITY COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIPS AND EXHIBITIONS
A Combined Examination for Natural Science Scholarships and Exhibitions will be held by the above Colleges, beginning on THURSDAY, NOVEMBER 14, 1898.

Three Scholarships and Two Exhibitions will be offered, the Scholarships being worth £20 a year.

The Subjects for Examination will be Physics, Chemistry, and Biology, but Candidates will not be expected to offer themselves in more than two of these.

Particulars may be obtained by application to
Christ Church, Oxford. A. VERNON HARCOURT

KING'S COLLEGE, LONDON.

Students in Arts and Science Engineering, Architecture, and Applied Sciences, Medicine, and other branches of Education will be admitted for the next Term (Tuesday), October 4. EVENING CLASSES commence Thursday, October 5.

Students are classed on entrance according to their proficiency, and terminal reports of the progress and conduct of Matriculated Students are sent to their parents and guardians. There are Entrance Scholarships and Exhibitions.

Students who are desirous of studying any particular subject or subjects, without attending the complete Course of the various Faculties, can be admitted as Non-Matriculated Students on payment of the Separate Fees for such Classes as they select.

There are a few Vacancies for Resident Students.
The College has an entrance both from the Strand and from the Thames Embankment, close to the Temple Station.
For Prospectus and all information apply to the SECRETARY, King's College, London, W.C.

UNIVERSITY OF GLASGOW. COURSES IN ENGINEERING SCIENCE

The Session opens on October 20.
NATURAL PHILOSOPHY—Prof. Lord Kelvin, D.C.L., F.R.S., M. Inst. C.E.
GEOLOGY—Prof. John Young, M.D.
CHEMISTRY—Prof. John Ferguson, M.A., LL.D.
MATHEMATICS—Prof. William Jack, M.A., LL.D.
ENGINEERING—Prof. Archibald Barr, D.Sc., M. Inst. C.E.
NAVAL ARCHITECTURE AND MARINE ENGINEERING—Prof. J. Harvard Biles, M.N.A.
ELECTRICAL ENGINEERING—Mr. John D. Cormack, B.Sc.

Prospectuses of the Courses, with Regulations for the Degrees of B.Sc. and D.Sc. in Engineering Science, and a List of Bursaries and Scholarships open to Science Students, can be had from the ASSISTANT CLERK

ENGINEERING AND CHEMISTRY. CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Instruction at the Institute's CENTRAL TECHNICAL COLLEGE (Exhibition Road) are for Students not under 16 years of age; those at the Institute's TECHNICAL COLLEGE, FINCHBURY, are of an Intermediate Grade for Students not under 14 years of age. The Entrance Examinations to both Colleges are held in September, and the Sessions commence in October. Particulars of the Entrance Examinations, Scholarships, Fees, and Courses of Study, may be obtained from the respective Colleges, or from the Head Office of the Institute, Gresham College, Basinghall Street, E.C.

CITY AND GUILDS CENTRAL TECHNICAL COLLEGE. (EXHIBITION ROAD, S.W.)

A College for higher Technical Instruction for Students not under 16 preparing to become Civil, Mechanical or Electrical Engineers, Chemical and other Manufacturers, and Teachers. Fees for a full Associateship Course, £45 per Session. Professors—

Civil and Mechanical Engineering	W. C. UNWIN, F.R.S., M. Inst. C.E.
Physics and Electrical Engineering	W. L. ARNOLD, F.R.S., Past Pres. Inst. E.E.
Chemistry	H. E. ARMSTRONG, Ph.D., LL.D.
Mechanics and Mathematics	O. HARRIS, Ph.D., LL.D., F.R.S.

CITY AND GUILDS TECHNICAL COLLEGE, FINCHBURY (LEONARD STREET, CITY ROAD, E.C.)

Provides Courses of Intermediate Instruction for Day Students not under 16 years of age, preparing to enter Engineering and Chemical Industries. Fees, £15 per Session. Professors—

Physics and Electrical Engineering	S. P. THOMPSON, D.Sc., F.R.S.
Mechanical Engineering and Mathematics	W. E. DAISY, M.A., B.Sc., M.I.M.E.
Chemistry	R. MELDOLA, F.R.S., F.I.C.

JOHN WATNEY, Hon. Secretary

City and Guilds of London Institute,
Gresham College, Basinghall Street, E.C.

BIRKBECK INSTITUTION, BREAMS BUILDINGS, CHANCERY LANE, E.C. Principal—G. ARMITAGE SMITH, M.A. DAY AND EVENING CLASSES.

The Session commences SEPTEMBER 28, 1898

UNIVERSITY OF LONDON—Completes Day Courses for all the Examinations in Science, and complete Evening Courses for all the Examinations for Science, Arts, and Law Degrees.

SCIENCE CLASSES in every branch, with Practical Work. Well equipped Laboratories.

LECTURES on Political Economy and Commercial Geography. CLASSES in Languages, Commercial and English Subjects, Common Law, Bankruptcy, Equity and Conveyancing, Logic, Psychology, and Ethics.

SCHOOL OF ART (Day and Evening) Drawing, Painting, Designing, Modelling, Life Classes, &c.

CIVIL SERVICE. Assistant Surveyor of Taxes, &c., Second Division, &c. Prospectus, Calendar (6d., Post free 8d.), and Syllabuses on application to the SECRETARY.

THE DURHAM COLLEGE OF SCIENCE. NEWCASTLE-UPON-TYNE.

Principal—Rev. H. P. GURNEY, M.A., D.C.L.

The College forms part of the University of Durham, and the University Degrees in Science and Letters are open to students of both sexes.

In addition to the Departments of Mathematics and Natural Science, complete Courses are provided in Agriculture, Engineering, Naval Architecture, Mining, Literature, History, Ancient and Modern Languages, Fine Art, &c.

Residential Hostels for men and for women Students are attached to the College.

The Twenty-ninth Session begins September 26, 1898.
Full particulars of the University Curricula in Science and Letters will be found in the Calendar (price 2s. 6d.) Prospectuses on application to the SECRETARY.

BEDFORD COLLEGE, LONDON (FOR WOMEN).

VORK PLACE, BAKER STREET, W.
HYGIENE AND PUBLIC HEALTH

The Course of Scientific Instruction, Practical and Theoretical, begins on Thursday, October 6, and extends over Three Terms.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

ELECTRICAL ENGINEERING.

Professor ANDREW GRAY, LL.D., F.R.S., will begin, in OCTOBER next, a systematic COURSE of INSTRUCTION in Electrical Measurement and Practical Electricity. The Physical Laboratory is fully equipped with a Compound Steam Engine, Dynamo, Transformer, Secondary Battery, and the most approved modern Measuring Instruments for all Branches of Electrical Engineering. **Lecturers' Fees at the rate of £12 per Term for six hours per week. Composition Fee for all College Lectures for the Session, £40.**

Applications for Calendar, Prospectus, and general information to be made to

J. E. LLOYD, M.A., Secretary and Registrar.

VICTORIA UNIVERSITY

THE YORKSHIRE COLLEGE, LEEDS.

The 45th Session of the Department of Science, Technology, and Arts will begin on October 11, and the 66th Session of the School of Medicine on October 3, 1898.

The Classes prepare for the following Professions: Chemistry, Civil, Mechanical, Electrical, and Sanitary Engineering, Mining, Textile Industries, Dyeing, Leather Manufacture, Agriculture, School Teaching, Medicine, and Surgery.

University Degrees are also conferred in the Faculties of Arts, Science, Medicine, and Surgery.
Lyddon Hall has been established for Students' residence.
Prospectus of any of the above may be had from the REGISTRAR.

HARTLEY COLLEGE, SOUTH-AMPTON.

SESSION 1898-99

PRINCIPAL—R. WALLACE STEWART, D.Sc. (London)

The Day Classes of the College include the following Courses:—

London University Courses in Arts and Science (Matriculation, Intermediate, and Final Courses in Arts and Science)
Science Courses for Medical Students and Dental Students
Mechanical Engineering Course
Electrical Engineering Course

NEXT SESSION COMMENCES ON SEPTEMBER 27, 1898

Prospectuses of above Courses may be obtained on application to the CLERK.

HARTLEY COLLEGE, SOUTH-AMPTON.

Applications are invited for the Post of ASSISTANT LECTURER and DEMONSTRATOR in PHYSICS and ELECTRICAL ENGINEERING.

A special knowledge of Experimental Physics or of Electrical Engineering, but not of both, is required.

Salary, £120 per annum.

Applications must be received on or before Saturday, September 17, 1898. Particulars may be obtained on application to the CLERK.

UNIVERSITY COLLEGE, LONDON.

The Session of the Faculty of Medicine will commence on October 3. Introductory Lecture, at 4 p.m., by Mr. SIDNEY BROWNE, Dental Surgeon to the Hospital.

The Examinations for the Entrance Exhibitions will commence on September 26.

Scholarships, Exhibitions, and Prizes of the value of £500 are awarded annually.
In University College Hospital about 3000 In-patients and 35,000 Out-patients are treated during the year. Thirty-six Appointments, eighteen being resident (on House Surgeon, House Physician, Obstetric Assistant, &c.), are filled up by competition during the year, and these, as well as all Clerks and Dressers, are open to students of the Hospital without extra fee. Resident Officers receive free board and lodging.
Prospectus, with full information as to Classes, Fees, &c., may be obtained from University College, Gower Street, W.C.

R. J. GODLEE, M.S., B.A., F.R.C.S., Dean
J. M. HORSBURGH, M.A., Secretary

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.

PRELIMINARY SCIENTIFIC CLASS.

Synopsis Course of Lectures and Laboratory Work in the subjects of the Preliminary Scientific and Intermediate B.Sc. Examinations of the University of London will commence on October 1, and continue till July, 1899.

Fee for the whole Course, £21, or £18 18s to Students of the Hospital, or single subjects may be taken.
There is a Special Class for the January Examination.
For further particulars apply to the Warden of the College, St. Bartholomew's Hospital, London, E.C.

A Handbook forwarded on application.

GUY'S HOSPITAL.

PRELIM. SCIENTIFIC (M.B. LONDON)

The next COURSE of LECTURES and PRACTICAL CLASSES for this Examination will begin on October 3. Candidates entering for this Course can register as Medical Students. Full particulars may be obtained on application to the DEAN, Guy's Hospital, London Bridge, S.E.

INSTRUCTION IN PURE CULTIVATION OF YEAST,

According to HANSEN'S Methods

Courses for Beginners, as well as for Advanced Students, in Physiology and Technology of Fermentations—Biological Analysis of Yeast.

Managers—R. Chr. Hansen. "Practical Studies in Fermentation" London (Spon), 1896. Alfred Jørgensen. "Micro-organisms and Fermentation" London (F. W. Lyon), 1892.

SCIENCE TUITION.

PREPARATION BY CORRESPONDENCE AND ORAL TUITION for all Science Examinations—Matriculation, B.Sc., Prel. Sci., &c. SINGLE SUBJECTS TAKEN—Chemistry, Physics, Botany, Zoology, &c. Special Classes in Botany and Chemistry.

TUTOR—The staff includes Graduates of London, Oxford, Cambridge, and Royal Universities.

For terms and testimonials, address Mr. J. CHARLINGTON, H.A., Building ton College, 27 Chancery Lane, London, W.C.

QUERNMORE, 24 CHANCERY LANE, W.C.

Tuition by JOHN GIBSON, M.A. (First Class, Camb.) and G. IOLY, B.A. (First Class, London), for all Public Examinations. Special Instruction in Scientific Agriculture for successful practical Agriculture and Forestry in the British Islands or the Colonies, as well as in Geology, Botany, &c., spontaneous and Higher Examination Journal gives up to date particulars of all the leading C.S. and other Examinations. Price 1d. post free. Prize of One Guinea for competition each month. Special Price of Five Guineas each June and December.

COUNTY BOROUGH OF DERBY,

MUNICIPAL TECHNICAL COLLEGE.

WANTED—(1) A Lecturer for the subjects of Inorganic Chemistry (Practical and Theoretical), Physiology and Hygiene. (2) A Lecturer for the subjects of Pure and Applied Mathematics, including Theoretical Mechanics, Sound, Light and Heat, and Electricity and Magnetism.

The Lecturers must be prepared to devote their whole time to the work. For Form of Application, and particulars of duties, send stamped addressed foolscap envelope to the SECRETARY.
Last day for Application, September 15.
Duties commence on October 3.

For continuation of Advertisements relating to Colleges, Schools, &c., see page cxlix.

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.

The Photo Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduc-
tion of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs.

The Instrument is fitted with
an Aluminium Body, 6-in
Azimuthal Circle, reading with
Vernier to one minute of arc,
4-in Compass, divided to half
degrees. Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description
of the Instrument sent free on application.

THE CAMBRIDGE NATURAL HISTORY.

Edited by B. F. HARMER, M.A., Fellow of King's College, Cambridge, Superintendent of the University Museum of Zoology; and A. E. SHIPLEY, M.A., Fellow of Christ's College, Cambridge, University Lecturer on the Morphology of Invertebrates.

To be completed in Ten Volumes. 8vo. Price 17s. net each.

Intended in all respects to be a Standard Natural History accurate enough to be of use to the Student, and at the same time popular enough for the general reader who desires trustworthy information as to the structure and habits of all members of the Animal Kingdom, from the Protozoa to the Mammals. The Volumes are fully illustrated by original figures drawn where possible from nature. When complete the Series is one which should be indispensable in all Libraries, whether public or private.

NOW READY

WORMS, LEECHES, etc.

VOLUME II

FLATWORMS By F. W. GAMBLE, M.Sc. Vict., Owens College
NEMERTINES By MISS L. SHELDON, Newnham College, Cambridge
THREAD-WORMS, &c. By A. E. SHIPLEY, M.A., Fellow of Christ's College, Cambridge
ROTIFERS. By MARCUS HARTOG, M.A. Trinity College, Cambridge, D.Sc. Lond., Professor of Natural History in the Queen's College, Cork.
POLYCHAET WORMS By W. BLAXIAND BENHAM, D.Sc. Lond., Hon. M.A. Oxon., Aldrichian Demonstrator of Comparative Anatomy in the University of Oxford
EARTHWORMS AND LEECHES By F. E. BEDDARD, M.A. Oxon., F.R.S., Prosector to the Zoological Society, London
GEPHYREA, &c. By A. E. SHIPLEY, M.A., Fellow of Christ's College, Cambridge
POLYZOA By S. F. HARMER, M.A., Fellow of King's College, Cambridge.

ACADEMY—"Of the importance of the new volume of the Cambridge Natural History there can be no doubt. It may be safely said that the information contained in it has never before been collected into one book, English or foreign. And all students of zoology will be grateful to the promoters of the Cambridge series for a treatise which will save them many a journey to the libraries and much weary searching in periodicals. For a long time to come this book will remain the best text book on the subject."

NATURE—"Taken as a whole the book is fully worthy of its place in this attractive series."

NATURAL SCIENCE—"Certain to prove a most welcome addition to English zoological literature. The whole is admirably illustrated. The index, to crown all, is a thoroughly good and full one."

CAMBRIDGE REVIEW—"We may say with confidence that the same amount of information, within the same compass, is to be had in no other zoological work."

SHELLS.

VOLUME III

MOLLUSCS AND BRACHIOPODS By the Rev. A. H. COOKE, M.A., A. E. SHIPLEY, M.A., and F. C. REED, M.A.

TIMES—"There are very many, not only among educated people who take an interest in science, but even among specialists, who will welcome a work of reasonable compass and handy form containing a trustworthy treatment of the various departments of Natural History by men who are familiar with, and competent to deal with, the latest results of scientific research. Altogether, to judge from this first volume, the Cambridge Natural History promises to fulfil all the expectations that its prospectus holds out."

FIELD—"We know of no book available to the general reader which affords such a vast fund of information on the structure and habits of molluscs."

KNOWLEDGE—"If succeeding volumes are like this one, the Cambridge Natural History will rank as one of the finest works on natural history ever published."

WESTMINSTER REVIEW—"Should find a place in the library of every naturalist."

INSECTS AND CENTIPEDES.

VOLUME V

PERIPATUS By ADAM SEDGWICK, M.A., F.R.S. **MYRIAPODS.** By F. G. SINCLAIR, M.A.
INSECTS Part I. By DAVID SHARP, M.A. Cantab., M.B. Edin., F.R.S.

FIELD—"Although written for the student and the specialist, the book is not the less adapted to all intelligent readers who wish to make themselves thoroughly acquainted with the habits, structure, and the modern classification of the animals of which it treats. To such it cannot be recommended too strongly."

ATHENÆUM—"This book will find a place in the library of most entomologists, prove a welcome boon to weak brethren who are compelled to lecture—*docendo discimus*—and occupy by the side of Westwood's 'Modern Classification' and Burmeister's 'Manual' a niche that has long been empty."

Prof. RAPHAEL MEIDOLA, F.R.S., F.C.S., in his Presidential Address to the Entomological Society of London, said—"The authors of this volume are certainly to be congratulated upon having furnished such a valuable contribution to our literature. When its successor appears, and I will venture to express the hope that this will be at no very distant period, we shall be in possession of a treatise on the natural history of insects which, from the point of view of the general reader, will compare most favourably with any similar work that has been published in the English language."

BIRDS.

VOLUME IX

By A. H. EVANS.

[Ready shortly.]

* * The next Volume to appear will be the completion of Dr. SHARP's admirable treatise on INSECTS. This may be looked for not later than January.

MACMILLAN AND CO, LIMITED, LONDON.

MACMILLAN & CO.'S BOOKS

FOR

STUDENTS OF ZOOLOGY.

A TEXT-BOOK OF ZOOLOGY. By T. JEFFERY PARKER, D.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, N.Z., and WILLIAM A. HASWELL, M.A., D.Sc., F.R.S., Professor of Biology in the University of Sydney, N.S.W. In Two Vols. With Illustrations. Medium 8vo, 36s net.

LITERATURE.—"The scheme of classification is on the whole so good that even those who find fault with matters of detail will admit its general excellence. The sections on Distribution—geographical, bathymetrical, and geological—and on The Philosophy of Zoology have been written with extreme care, the latter especially being full of pregnant remarks and suggestions. A useful chapter on the History of Zoology is appended, from which a true idea of the perspective of things can be gathered. Other volumes are copiously indexed, and reference to any heading is thus made easy."

A TEXT-BOOK OF ENTOMOLOGY, including the Anatomy, Physiology, Embryology and Metamorphoses of Insects, for use in Agricultural and Technical Schools and Colleges, as well as by the working Entomologist. By ALPHÉUS S. PACKARD, M.D., Ph.D., Professor of Zoology and Geology, Brown University. Medium 8vo, 18s net.

NATURE.—"Dr Packard's book will be of the greatest service to students of insect anatomy, and almost indispensable to future writers on the subject. It should find a place in every library which includes comparative anatomy, and should be the constant companion of all who occupy themselves with the structure and life histories of insects."

ESSAYS ON MUSEUMS AND OTHER SUBJECTS CONNECTED WITH

NATURAL HISTORY. By SIR WILLIAM HENRY FLOWER, K.C.B., D.C.L., D.Sc., LL.D., Ph.D., F.R.S., F.R.C.S., F.Z.S., Correspondent of the Institute of France, &c. Demy 8vo, 12s net.

ATHENÆUM.—"Many of these essays possess permanent value, and all are well worthy of being printed afresh."

A TEXT-BOOK OF COMPARATIVE

ANATOMY. By DR ARNOLD LANG, Professor of Zoology in the University of Zürich. With Preface to the English Translation by DR ERNST HAECKEL. Translated by HENRY M. BERNARD, M.A. Cantab., and MARIETTA BERNARD. Vols I and II (completing the Invertebrates.) 8vo 17s net each.

LESSONS IN ELEMENTARY ANATOMY

By ST GEORGE MIVART, F.R.S., Author of "The Genesis of Species." Fcap 8vo 6s 6d.

ELEMENTS OF THE COMPARATIVE

ANATOMY OF VERTEBRATES. Adapted from the German of ROBERT WIEDEBNEIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Freiburg, in Baden. By W. NEWTON PARKER, Professor of Biology in the University College of South Wales and Monmouthshire. With additions by the Author and Translator. 270 Woodcuts. Medium 8vo. Second Edition. 12s 6d net.

The STRUCTURE of MAN An IN-

DEX to his PAST HISTORY. By ROBERT WIEDEBNEIM. Translated by H. and M. BERNARD. The Translation, Edited and Annotated, and a Preface written by G. B. HOWES, F.R.S., Professor of Zoology, Royal College of Science, London. With 105 Figures in the Text. 8vo 8s net.

A COURSE OF INSTRUCTION in

ZOOLOGY. Vertebrata. By T. JEFFERY PARKER, F.R.S., Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo. 8s 6d.

An INTRODUCTION to the OSTE-

LOGY OF THE MAMMALIA. By SIR WILLIAM HENRY FLOWER, F.R.S., F.R.C.S., Director of the Natural History Department of the British Museum. Illustrated. Third Edition. Revised with the assistance of HANS GADOW, Ph.D., Lecturer on the Advanced Morphology of Vertebrates in the University of Cambridge. Crown 8vo. 10s 6d.

A TREATISE ON COMPARATIVE

EMBRYOLOGY. By the late Prof F. M. BALFOUR, M.A., F.R.S. In two Vols. Second Edition. Medium 8vo. Vol I 18s. Vol II 21s.

The ELEMENTS of EMBRYOLOGY.

By Prof MICHAEL FOSTER, M.D., F.R.S., and the late Prof F. M. BALFOUR, F.R.S. Second Edition, revised. Edited by A. SEDGWICK, M.A., and W. HICKAP, M.A. Illustrated. Crown 8vo 10s 6d.

STRUCTURE AND LIFE of BIRDS.

By F. W. HEADLEY, Assistant Master at Haileybury College. Illustrated. Crown 8vo 7s 6d.

The NATURAL HISTORY of the

MARKETABLE MARINE FISHES of the BRITISH ISLANDS. By J. T. CUNNINGHAM, M.A. With Preface by E. RAY LANKESTER, F.R.S. Illustrated. Medium 8vo 7s 6d net.

NATURAL HISTORY of AQUATIC

INSECTS. By L. C. MIALL, F.R.S., Professor of Biology in the Yorkshire College, Leeds. Illustrated. Crown 8vo 6s.

THE ORIGIN AND METAMOR-

PHOSES of INSECTS. By SIR JOHN LUBBOCK, F.R.S. With Illustrations. 3s 6d. [Nature Series]

MONOGRAPH of the BRITISH

CICADÆ or TETTIGONIDÆ (hoppers and Grasshoppers). By GEORGE BOWDLER BUCKTON, F.R.S., Illustrated by more than 400 Coloured Drawings. Two Vols. Demy 8vo 33s 6d each, net. Also in Eight Parts 8s each, net.

A HANDBOOK OF BRITISH LE-

PIDOPTERA. By EDWARD MEYRICK, B.A., F.Z.S., F.E.S., Assistant Master at Marlborough College. Extra Crown 8vo. 10s 6d net.

MACMILLAN & CO.'S BOOKS FOR HOLIDAY READING.

ALFRED LORD TENNYSON: a Memoir. By his SON. With Photogravure Portraits. 2 vols. Medium 8vo 36s. net

MR. BODLEY'S FRANCE. In 2 vols. Demy 8vo 21s. net.

EDINBURGH REVIEW—"He has devoted himself to his task with great ability and the most praiseworthy industry. He has endeavoured to divest himself of English prejudice, and he writes in the character of an impartial and close observer of French political and social life for seven long years and as a devoted friend of the French people. . . Mr. Bodley's book will be read by all men, and deserves to be read with care and discrimination."

A HISTORY OF THE INDIAN MUTINY, AND OF THE DISTURBANCES

WHICH ACCOMPANIED IT AMONG THE CIVIL POPULATION. By T. RICE HOLMES. Fifth Edition, revised throughout and slightly enlarged. With Maps and Plans. Extra Crown 8vo 12s. 6d.
"T. P." in the *WEEKLY SUN* says—"It is but a poor and an insufficient compliment to say that the book is more interesting than any work of fiction. For myself I have read it as breathlessly as though it were an exciting novel; with that added sense that I was reading of reality and not of fiction. . . Impartiality, profound knowledge, a charming style, unassailable accuracy—these are qualities that are not often found in combination; they are found in this noteworthy volume."

HENRY OF GUISE AND OTHER PORTRAITS. By H. C. MACDOWALL. Extra Crown 8vo 8s. 6d. net

DAILY NEWS—"The book is full of dramatic interest and may be confidently recommended to readers who have a taste for the romance of history."

LIFE AND LETTERS OF WILLIAM JOHN BUTLER, late Dean of Lincoln, and sometime Vicar of Wantage. With Portraits Demy 8vo 12s. 6d. net

LITERATURE—"This biography is one of exceptional interest, and we trust that it will be widely and attentively studied."

HIGHWAYS AND BYWAYS IN DEVON AND CORNWALL. By ARTHUR H. NORWAY. With Illustrations by JOSEPH PENNY and HUGH THOMSON. Extra crown 8vo 6s.

GUARDIAN—"One of the prettiest and best books of the season."

By THE RIGHT HON. JAMES BRYCE, M.P.

IMPRESSIONS OF SOUTH AFRICA. By the Right Hon. JAMES BRYCE, M.P.,

Author of "The Holy Roman Empire," &c. With Three Maps. Demy 8vo 14s. net
THE TIMES—"There are few who will not lay down the volume feeling that they know more than they ever expected or hoped to know upon the subject of which it treats."

SOUTH AFRICA OF TO-DAY. By Captain FRANCIS YOUNGHUSRAND, C.I.E., Indian Staff Corps, late Special Correspondent of *The Times* in South Africa, Author of "The Relief of Chitral." With Illustrations. Demy 8vo 8s. 6d. net

SPECTATOR—"Admirably fair and lucid. The sanest and most statesmanlike work that has yet appeared on the South African problem."

CARD AND SLIP FILES.

Portion of Card File

The Ceres Card Files in Cabinets (with rod) for Library Catalogues, and in Boxes and Trays (without the rod) for other purposes, constitute the latest development of the Card System

The Bishop of Bristol:—"The convenience of the Writing Table with 'Ceres' Files is beyond words. So far as I can keep pace with my correspondence, there is never anxiety as to where a letter is, and the drawer with cards for notes of references, speeches, sermons, &c., makes me perpetually regret that I had not such a thing twenty years ago."

Sir H. H. Bemrose, M.P.:—"I am using the Card Box daily for a literary purpose, and I find it simply invaluable. As it lies on the table entries are made at the moment under their proper heads, and the facility of reference is such as no other mode of indexing I am aware of can touch."

For other varieties and sizes of Box Files, Cabinets, Writing Tables, Standing Desks, Card Files, &c., see Explanatory Pamphlet, Post Free

NEWMAN & GUARDIA, Ltd.,
90 & 92 Shaftesbury Avenue, London, W

JAS. J. HICKS, 8, 9 & 10 HATTON GARDEN, LONDON,

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special
construction, and a simple and accurate arterial pressure gauge.
It is marvellously sensitive, and consists of a metal tambour,
the expansion of which is exhibited in a highly magnified form
by means of an index or pointer which travels round a dial.
This dial is graduated in millimetres of mercury. The armlet
pump and pressure gauge, when not in use, fit conveniently into
a leather case. By means of this instrument we believe that
the arterial pressure can be taken in man as rapidly, simply, and
accurately as the temperature can be taken with the clinical
thermometer

Price 25s. Spare Bag and Tube, 5s.

The Instrument has a 5-in. Dial, and is packed in a
neat morocco Case with Handle.

BROWNING'S PLATYSCOPIC LENS With Larger Angles Increased Field and Improved Definition

to give a real or
AN ACHROMATIC COMBINATION

COMBINING THE DEFINITION OF A MICROSCOPE WITH THE
PORTABILITY OF A LOCKET LENS

If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do) — *WANT A LENS? KNOWLEDGE*
The Platyscopic Lens is invaluable to botanists, mineralogists or entomologists, as it gives about three times as far from the object as the Coolidge lens, and all we require objects to be examined easily.

The Platyscopic Lens gives of 10 degrees of power magnifying respectively 10, 15, 20, and 30 times, the lowest power being the largest field, is the best required for general use.

The Lenses are set in Ribbon Cellulose and mounted in Tortoise-shell Frames.
Price of the Platyscopic Lens mounted in Tortoise-shell magnifying either 10, 15, 20 or 30 diameters 18s 6d each power.

Illustrated description sent free.

Students of both sexes are admitted. There is no Entrance examination. Scholarships, &c., of the value of £200 are offered for competition annually. The Regulations as to these, and further information as to Classes, Prizes, &c., may be obtained from

M. HORSBURGH, M.A., Secretary

TECHNICAL CLASSES

THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE

The Diploma of the College is granted in the following Departments of Engineering and other branches of Applied and General Sciences—

CIVIL ENGINEERING	CHEMICAL ENGINEERING
MECHANICAL ENGINEERING	METALLURGY
NAVAL ARCHITECTURE	MINING ENGINEERING
ELECTRICAL ENGINEERING	AGRICULTURE
ARCHITECTURE	MATHEMATICS AND PHYSICS

Special Courses of Study extending over three Academic years have been arranged in each of the above Departments. Average Fee per Session, £14 14s.

Students may enrol in any of the separate Courses of Lectures, or in any of the Laboratories, provided they are qualified to take advantage of the instruction given.

The Laboratories for Practical Instruction in Physics, Chemistry, Technical Chemistry, Metallurgy, and Electrical Engineering, and the Engineering Workshop, are literally equipped with the most approved Apparatus.

Session 1898-99 commences on MONDAY, OCTOBER 5. Entrance Examination begins on TUESDAY, SEPTEMBER 27.

For Calendar (price 1d. by Post), containing detailed Syllabuses of each Course, particulars of Fees, Scholarships, &c., apply to JOHN YOUNG, B.Sc., Secretary

at Bath Street, Glasgow

BEDFORD COLLEGE, LONDON (FOR WOMEN),

WORK PLACE, BAKER STREET, W

Principal Miss ETHEL HURBATT

The Session for 1898-99 begins on Thursday, OCTOBER 6. Students are expected to enter their names between 2 and 4 o'clock on Wednesday, October 5.

The Introductory Lecture will be delivered at 4.30 p.m. on Thursday, October 6.

Further information on application to the PRINCIPAL

UNIVERSITY OF ST. ANDREWS.

SESSION 1898-99

FACULTY OF MEDICINE

PRELIMINARY EXAMINATION

The Preliminary Examination in Medicine will take place at the United College, St. Andrews, on October 3, 4, and 5. Each Candidate must apply to the Secretary for a schedule, to be filled up and returned not later than September 26. The subjects of examination are—English, Latin, Elementary Mathematics, and Greek or French or German, and the Fee is Half a Guinea.

BURSARIES OPEN TO COMPETITION

Twelve Barry Bursaries of the annual value of £50 each, tenable for two years, restricted to Male Medical students.

Fourteen Taitoun Thomson Bursaries, of the annual value of £50 to £70 each, tenable partly for one year and partly for two years, restricted to Female Medical Students.

Schedules of applications, subjects of examination, and conditions of tenure may be obtained from the SECRETARY, up to September 19.

MEDICAL CLASSES

The Classes in the Faculty of Medicine will be opened for the Winter Session on Wednesday, October 12.

The printed regulations and all information as to Matriculation, Class Fees, &c., may be had on application to

J. MAITLAND ANDERSON, Secretary

Further information regarding Fees, Scholarships, and Courses of Study may be had from the College Calendar, or on application to the REGISTRAR. The Principal will be in attendance at the College on Thursday, September 29, and following days, for the purpose of enrolling Students and giving information regarding Courses of Study.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE

CHAIRMAN OF THE COUNCIL LORD LISTER, F.R.S.

The WINTER SESSION commences on Tuesday, October 4, when the New Laboratories of the Institute will be available for investigation and instruction in the following branches of work—

1. Bacteriology in relation to Medicine and Pathology
2. Bacteriology in relation to Hygiene
3. Bacteriology of Fermentation Processes
4. Biological Chemistry
5. Photomicrography

A Practical Course, illustrating the Principles of Hygiene, will be given in the Bacteriological and Chemical Laboratories, and will include all the Laboratory Instruction necessary for the Diploma in Public Health. Facilities and help will be given to those wishing to carry out original investigations in connection with Bacteriology or Hygiene.

Further particulars on application to Chelsea Bridge, S.W.

NAVAL ARCHITECTURE AND MARINE ENGINEERING—Prof. J. Harvard

Blin, M. I. N. A.

ELECTRICAL ENGINEERING—Mr. John D. Cormack, B.Sc.

Prospectuses of the Courses, with Regulations for the Degrees of B.Sc. and D.Sc. in Engineering Science, and a List of Bursaries and Scholarships open to Science Students, can be had from the ASSISTANT CLERK.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S E

The WINTER Session of 1898-99 will open on MONDAY October 3, when the prizes will be distributed at 3 p.m. by the Right Rev the Lord Bishop of Rochester in the Governors' Hall.

Three Entrance Scholarships will be offered for competition in September, viz.—One of £150 and one of £60 for Chemistry and Physics, with either Physiology, Botany, or Zoology, for first year students, one of £50 in Anatomy, Physiology, and Chemistry, for third year students, from the Universities.

Scholarships and money prizes of the value of £300 are awarded at the Sessional Examinations, as well as several medals.

Special Classes are held throughout the year for the Preliminary Scientific and Intermediate M.B. Examinations of the University of London.

All Hospital Appointments are open to Students without charge.

Club Rooms and an Athletic Ground are provided for Students.

The School Buildings and the Hospital can be seen on application to the Medical Secretary.

The Fees may be paid in one sum or by instalments. Prizes may be made separately to Lectures or to Hospital Practice, and Special Arrangements are made for Students entering from the Universities and for Qualified Practitioners.

A Register of approved Lodgings is kept by the Medical Secretary, who also has a List of Local Medical Practitioners, Clergymen, and others who receive Students into their houses.

For Prospectus and all particulars apply to Mr. RENDLE, the Medical Secretary.

H. P. HAWKINS, M.A., M.D. Oxon, & Lenn

GUY'S HOSPITAL MEDICAL SCHOOL.

The WINTER Session will begin on MONDAY, OCTOBER 3. Entrance Scholarships of the combined value of £400 are awarded annually, and numerous Prizes and Medals are open for Competition by Students of the School.

The number of Patients treated in the Wards during last year exceeded 6000.

All Hospital Appointments are made strictly in accordance with the merits of the Candidates, and without extra payment. There are 38 Resident Appointments open to Students of the Hospital annually without payment of additional fees, and numerous Non-Resident Appointments in the General and Special Departments.

The Queen Victoria Ward, recently re-erected, will provide additional accommodation for Gynaecological and Maternity cases.

The College accommodates 60 Students, under the supervision of a Resident Warden.

The Dental School provides the full Curriculum required for the L.D.S. England.

The Clubs Union Athletic Ground is easily accessible.

A Handbook of Information for those about to enter the Medical Profession will be forwarded on application.

For the Prospectus of the School, containing full particulars as to Fees, Course of Study advised, Regulations of the College, &c., apply, personally or by letter, to the DEAN, Guy's Hospital, London Bridge, S.E.

VICTORIA UNIVERSITY

THE YORKSHIRE COLLEGE, LEEDS.

MEDICAL DEPARTMENT

The WINTER Session, being the Sixty eighth of the Leeds School of Medicine will OPEN October 3, 1898, at 5 p.m., when an Address will be delivered and the Prizes distributed by Dr. C. J. CUTTINGWORTH, D.C.L., F.R.C.P., President of the Obstetrical Society of London, Oculist, Physician to St. Thomas's Hospital.

The Lectures and Hospital Practice qualify Students for the various Examining Boards. Students can enter for the Hospital Practice or the Lectures, or for a single Course of Lectures separately.

The Infirmary, in which the medical and surgical practice is conducted, has an average of 400 in-patients. Senior Students are selected according to merit for several resident appointments. Other Institutions are also open to Students.

Prizes are awarded at the Sessional Examinations. The Prospectus and particulars of Entrance Scholarships may be obtained from the REGISTRAR of the College.

VICTORIA UNIVERSITY

THE YORKSHIRE COLLEGE, LEEDS.

The 45th Session of the Department of Science, Technology, and Arts will begin on October 21, and the 58th Session of the School of Medicine on October 3, 1898.

The Classes prepare for the following Professions: Chemistry, Civil, Mechanical, Electrical, and Sanitary Engineering, Mining, Textile Industries, Dyeing, Leather Manufacture, Agriculture, School Teaching, Medicine, and Surgery.

University Degrees are also conferred in the Faculties of Arts, Science, Medicine, and Surgery.

Lyddon Hall has been established for Students' residence. Prospectus of any of the above may be had from the REGISTRAR.

THE SANITARY INSTITUTE.

The Seventeenth Congress and Health Exhibition will be held in Birmingham from September 27 to October 1, under the Presidency of Sir JOSIAH FAYRE, Bart., K.C.S.I., LL.D., M.D., F.R.S.

Programme and other particulars can be obtained of the Local Secretaries: TAYLOR, Council House, Birmingham, or at the Offices of the Institute, Margaret Street, London W.

E. WHITE WALKER, Secretary

BIRKBECK INSTITUTION,

BREAMS BUILDINGS, CHANCERY LANE, E.C.

Principal—G. ARMITAGE SMITH, M.A.

DAY AND EVENING CLASSES

The Session commences SEPTEMBER 28, 1898

UNIVERSITY OF LONDON.—Complete Day Courses for all the Examinations in Science, and complete Evening Courses for all the Examinations for Science, Arts, and Law Degrees.

SCHOOL OF ARTS (Day and Evening).—Drawing, Painting, Designing, Modelling, Life Classes, &c.

LECTURES ON Political Economy and Commercial Geography. CLASSES in Languages, Commercial and English Subjects, Common Law, Bankruptcy, Equity and Conveyancing, Logic, Psychology, and Ethics.

CIVIL SERVICE.—Assistant Surveyor of Taxes, &c., Second Division, &c.

PROSPECTUS, Calendar (free), Post free 3d., and Syllabuses on application to the SECRETARY.

THE DURHAM COLLEGE OF SCIENCE,

NEWCASTLE-UPON-TYNE

Principal—Rev H. P. GURNEY, M.A., D.C.L.

The College forms part of the University of Durham, and the University Degrees in Science and Letters are open to Students of both sexes.

In addition to the Departments of Mathematics and Natural Science, complete Courses are provided in Agriculture, Engineering, Naval Architecture, Mining, Literature, History, Ancient and Modern Languages, Fine Arts, &c.

Residential Hostels for men and for women students are attached to the College.

The Twenty eighth Session begins September 28, 1898.

Full particulars of the University Curriculum in science and Letters will be found in the Calendar (price 1s. 6d.). Prospectuses on application to the SECRETARY.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

ELECTRICAL ENGINEERING

Professor ANDREW GRAY, F.R.S., D.C.L., will begin, in OCTOBER, a systematic COURSE of INSTRUCTION in Electrical Measure and Practical Electricity. The Physical Laboratory is fully equipped with a Compound Steam Engine, Dynamo, Transformer, secondary battery, and the most improved modern measuring instruments for all branches of Electrical Engineering. Laboratory Fees at the rate of £1 1s per term for six hours per week. Composition fee for all College Lectures for the Session £10.

Applications for Calendar, Prospectus, and general information to be made to

J. B. LLOYD, M.A., Secretary and Registrar

UNIVERSITY COLLEGE, LONDON.

LECTURES ON ZOOLOGY

The General Course of Lectures on Zoology, by Prof. W. F. R. WELDON, F.R.S., will commence on Wednesday, October 5, at one o'clock.

A special course of Lectures on Entomology, suitable for Candidates for the B.Sc. Degree, under the new regulations of the University of London will commence on Tuesday, October 11, at one o'clock, and will be continued on Tuesdays throughout the Session.

apparatus, 45/10s. **FREE Lessons to Photographers.**

From R. BOWDLER SHARPE, Esq., LL.D., Assistant Keeper, Zoological Department, British Museum

"I have received the remainder of the proofs of my photographs, and I must say that I am delighted with
them. I consider it one of the best days' work I ever did when I bought one of your 'Binocular' Camera.
The ease with which it is worked, and the excellent results obtained, make it a most pleasurable accompani-
ment of a summer's outing, and, in my case, 90 per cent. of my Norway photographs have come out beauti-
fully, while even the small remainder cannot be considered failures. I think this is a grand result, when you
remember that I had little or no experience of photography, and had only time for an hour's instruction in
your rooms the day before I sailed, and, further, that I had to make my own dark room in Norway in the
best way I could. I am looking forward to having much pleasure this summer from the faithful 'Binocular',
and I have recommended it to all my friends."

PRACTICAL ORGANIC CHEMISTRY. By GEORGE GEORGE, F.C.S.

FOR THE ADVANCED STAGE 3s. 6d. each Vol

ADVANCED MECHANICS Vol I, DYNAMICS By WILLIAM BRIGGS, M.A., F.C.S., F.R.S., and G. H. BRYAN, Sc.D., M.A., F.R.S.

ADVANCED MECHANICS. Vol II, STATICS By WILLIAM BRIGGS, M.A., F.C.S., F.R.S., and G. H. BRYAN, Sc.D., M.A., F.R.S.

ADVANCED HEAT. By R. WALLACE STEWART, D.Sc., Lond.

SECOND STAGE MATHEMATICS (being the additional Algebra and Euclid, with the Trigonometry required for the Second Stage). Edited by WILLIAM BRIGGS, M.A., F.C.S., F.R.S.

COMPLETE CATALOGUE of over 450 Books specially adapted for London University and other Examinations

LONDON W. B. CLIVE, 13 BOOKSELLERS ROW, STRAND, W.C.

MACMILLAN & CO.'S BOOKS FOR STUDENTS OF ANATOMY, PHYSIOLOGY, AND EMBRYOLOGY.

TEXT-BOOK OF PATHOLOGICAL

ANATOMY AND PATHOGENESIS By Prof ERNST ZIEGLER, of Tübingen Translated and Edited for English Students by DONALD MACALISTER, M.A., M.D., B.Sc., F.R.C.P. With Illustrations Part I—General Second Edition. 12s 6d Part II—Special Sections I.—VIII Third Edition 17s net Sections IX.—XV 17s net

A TEXT-BOOK of COMPARATIVE

ANATOMY. By Dr. ARNOLD LANG, Professor of Zoology in the University of Zürich With Preface to the English Translation by Dr ERNST HAECKEL Translated by HENRY M. BERNARD, M.A. Cantab., and MARILDA BERNARD Vols I and II (completing the Invertebrates) 8vo 17s net each.

LESSONS in ELEMENTARY AN-

ATOMY By ST. GEORGE MIVART, F.R.S., Author of "The Genesis of Species" Fcap 8vo 6s 6d

ELEMENTS of the COMPARATIVE

ANATOMY OF VERTEBRATES Adapted from the German of Dr. ROBERT WIEDERSHEIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Freiburg, in Baden By Prof W. N. PARKER Second Edition 12s 6d net

THE STRUCTURE of MAN. An IN-

DEX to his PAST HISTORY By ROBERT WIEDERSHEIM Translated by H. and M. BERNARD The Translation, Edited and Annotated, and a Preface written by G. B. HOWES, F.R.S., Professor of Zoology, Royal College of Science, London With 105 Figures in the Text 8vo 8s net

A COURSE of INSTRUCTION in

ZOOLOGY Vertebrata By T. JEFFERY PARKER, F.R.S., Professor of Biology in the University of Otago, New Zealand With Illustrations. Crown 8vo. 8s 6d

An ATLAS of PRACTICAL ELE-

MENTARY BIOLOGY By G. B. HOWES With a Preface by the Right Hon. T. H. HUXLEY, F.R.S. 14s

ELEMENTARY BIOLOGY. By T. H.

HUXLEY, F.R.S., and H. N. MARTIN, F.R.S. New Edition Revised and extended by G. B. HOWES and D. H. SCOTT 10s 6d

LESSONS in ELEMENTARY

BIOLOGY. By Prof T. JEFFERY PARKER, B.Sc., F.R.S. Illustrated Third Edition, revised 10s 6d

TEXT-BOOK of PHYSIOLOGY By

Prof MICHAEL FOSTER, M.D., F.R.S. With Illustrations Fifth Edition, largely revised In Four Parts. Part I. Blood—The Tissues of Movement, the Vascular Mechanism 10s 6d Part II The Tissues of Chemical Action, with their Respective Mechanisms—Nutrition. 10s 6d Part III The Central Nervous System 10s 6d Part IV The Senses and some Special Muscular Mechanisms The Tissues and Mechanisms of Reproduction. 10s 6d Appendix By A. S. LEA 7s 6d

LESSONS in ELEMENTARY PHY-

SIOLGY By THOS. H. HUXLEY, F.R.S. Illustrated New Edition, revised 4s 6d Questions, 1s 6d.

PHYSIOLOGY. By MICHAEL FOSTER,

M.D., F.R.S. With Illustrations Pott 8vo. 1s [Science Primers.]

PHYSIOLOGY for BEGINNERS. By

M. FOSTER, M.D., F.R.S., Professor of Physiology in the University of Cambridge, and LEWIS E. SHORE, M.A., M.D., Fellow of St. John's College, Cambridge, and Senior Demonstrator of Physiology in the University of Cambridge Globe 8vo 2s 6d

A TEXT-BOOK of the PHYSIO-

LOGICAL CHEMISTRY OF THE ANIMAL BODY, including an Account of the Chemical Changes occurring in Disease By ARTHUR GAMGEE, M.D., F.R.S. In Two Vols Vol I, 18s Vol II, 18s.

PRACTICAL PHYSIOLOGY AND

HISTOLOGY AN ELEMENTARY COURSE By Prof M. FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. 7s 6d

ELECTRO-PHYSIOLOGY. By Prof.

W. BIEDERMANN Translated by F. A. WELBY. Vols I and II, 17s net each

COMPARATIVE EMBRYOLOGY:

A TREATISE ON By F. M. BALFOUR, M.A., F.R.S. Illustrated In Two Vols. Vol I, 18s Vol II, 21s.

The ELEMENTS of EMBRYOLOGY.

By Prof M. FOSTER, M.D., F.R.S., and the late FRANCIS M. BALFOUR, F.R.S. Second Edition, revised Edited by ADAM SKEWICH, M.A., and WALTER HEAPE 10s 6d

LESSONS in ELEMENTARY AN-

ATOMY. By ST. GEORGE MIVART, F.R.S. With 400 Illustrations 6s 6d

A TEXT-BOOK of ZOOLOGY. By

Prof T. JEFFERY PARKER, B.Sc., F.R.S., and Prof. W. A. HASWELL In Two Vols 36s net.

IMPORTANT SCIENTIFIC WORKS FOR SALE.

ANNALES DE CHIMIE ET DE PHYSIQUE. A Complete Set, consisting of First, Second, Third, Fourth, and Fifth Series to Vol. 30, with Indices, &c. 299 vols., 274 in 24, half calf, and 35 vols. unbound (yearly number for January 1853, 1799-1883). 46s.

PHILOSOPHICAL MAGAZINE. First Series, Vols. 1 to 38 Second and Third Series complete Fourth Series, Vols. 1 to 42 24 volumes in old half calf, the rest unbound 1798-1871 63s.

Down to Fourth Series, Vol. 12, the volumes have the stamp of an Institution now dissolved. A few volumes of the First Series are stained, and five plates are wanting in the First Series. All portraits, &c., are contained in this copy, which is marked at a very moderate price because of its condition.

ARCHIV FÜR DIE GESAMMTE PHYSIOLOGIE DES MENSCHEN UND DER THIERE. Hrg. v. F. W. PFLÜGER. 8vo. Bdin. 3-12 cloth, 13 and 14 half morocco, 16, 17, 23-37 and Index to Bdin. 1-30 in Nov. In all 99 vols. and Index 1859-82 12s.

JOURNAL OF PHYSIOLOGY. Edited by Prof. MICHAEL FOSTER. Vols. I-XX, 3 1878-August, 1896 (I-XI half morocco, rest in Nov.) Numerous plates, &c., & 14 14s.

Complete set in fine condition, with the scarce supplements, &c. We have also several duplicate volumes and numbers.

BRONN, H. G. Die Klassen und Ordnungen des Thier-Reichs in Wort und Bild. Bdin II Lf. 2-5, 10-12, III Abt. 1 and a half calf IV Lf. 18-47, V Abt. 1 in half calf and Nov., Abt. 2, Lf. 1-6, VI Abt. 1, Lf. 1-4, Abt. 2 complete, Abt. 3, Lf. 1-6, Abt. 4, Lf. 1-4, Abt. 5, Lf. 1-4, 15-44 Numerous plates. 8vo. 42s 12s.

BALFOUR, FRANCIS MAITLAND. Works. Memorial Edition, edited by M. FOSTER and A. SEDGWICK. 4 vols. Roy. 8vo, 1885 42s.

BALFOUR, FRANCIS MAITLAND. Studies from the Morphological Laboratory in the University of Cambridge. Plates a parts. 8vo 1886-82 12s.

Papers by F. M. Balfour, Adam Sedgwick, W. N. Parker, S. J. Huxton, &c.

LANKESTER, E. RAY. Zoological Articles contributed to the "Encyclopædia Britannica." 4to, cloth 1891 Out of print 12s 6d.

ROYAL SOCIETY. PHILOSOPHICAL TRANSACTIONS, at large, 1764, 1766, 1768 to 1891 123 vols. and Indices to vols. 1 to 110, 3 vols. The Transactions, 1665-1800, abridged by HUTTON, 1810, and 1811, 1812, 1813, 1814, 1815, 1816, 1817, 1818, 1819, 1820, 1821, 1822, 1823, 1824, 1825, 1826, 1827, 1828, 1829, 1830, 1831, 1832, 1833, 1834, 1835, 1836, 1837, 1838, 1839, 1840, 1841, 1842, 1843, 1844, 1845, 1846, 1847, 1848, 1849, 1850, 1851, 1852, 1853, 1854, 1855, 1856, 1857, 1858, 1859, 1860, 1861, 1862, 1863, 1864, 1865, 1866, 1867, 1868, 1869, 1870, 1871, 1872, 1873, 1874, 1875, 1876, 1877, 1878, 1879, 1880, 1881, 1882, 1883, 1884, 1885, 1886, 1887, 1888, 1889, 1890, 1891, 1892, 1893, 1894, 1895, 1896, 1897, 1898, 1899, 1900, 1901, 1902, 1903, 1904, 1905, 1906, 1907, 1908, 1909, 1910, 1911, 1912, 1913, 1914, 1915, 1916, 1917, 1918, 1919, 1920, 1921, 1922, 1923, 1924, 1925, 1926, 1927, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1942, 1943, 1944, 1945, 1946, 1947, 1948, 1949, 1950, 1951, 1952, 1953, 1954, 1955, 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970, 1971, 1972, 1973, 1974, 1975, 1976, 1977, 1978, 1979, 1980, 1981, 1982, 1983, 1984, 1985, 1986, 1987, 1988, 1989, 1990, 1991, 1992, 1993, 1994, 1995, 1996, 1997, 1998, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022, 2023, 2024, 2025, 2026, 2027, 2028, 2029, 2030, 2031, 2032, 2033, 2034, 2035, 2036, 2037, 2038, 2039, 2040, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2049, 2050, 2051, 2052, 2053, 2054, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2063, 2064, 2065, 2066, 2067, 2068, 2069, 2070, 2071, 2072, 2073, 2074, 2075, 2076, 2077, 2078, 2079, 2080, 2081, 2082, 2083, 2084, 2085, 2086, 2087, 2088, 2089, 2090, 2091, 2092, 2093, 2094, 2095, 2096, 2097, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2119, 2120, 2121, 2122, 2123, 2124, 2125, 2126, 2127, 2128, 2129, 2130, 2131, 2132, 2133, 2134, 2135, 2136, 2137, 2138, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2174, 2175, 2176, 2177, 2178, 2179, 2180, 2181, 2182, 2183, 2184, 2185, 2186, 2187, 2188, 2189, 2190, 2191, 2192, 2193, 2194, 2195, 2196, 2197, 2198, 2199, 2200, 2201, 2202, 2203, 2204, 2205, 2206, 2207, 2208, 2209, 2210, 2211, 2212, 2213, 2214, 2215, 2216, 2217, 2218, 2219, 2220, 2221, 2222, 2223, 2224, 2225, 2226, 2227, 2228, 2229, 2230, 2231, 2232, 2233, 2234, 2235, 2236, 2237, 2238, 2239, 2240, 2241, 2242, 2243, 2244, 2245, 2246, 2247, 2248, 2249, 2250, 2251, 2252, 2253, 2254, 2255, 2256, 2257, 2258, 2259, 2260, 2261, 2262, 2263, 2264, 2265, 2266, 2267, 2268, 2269, 2270, 2271, 2272, 2273, 2274, 2275, 2276, 2277, 2278, 2279, 2280, 2281, 2282, 2283, 2284, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2292, 2293, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2306, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2314, 2315, 2316, 2317, 2318, 2319, 2320, 2321, 2322, 2323, 2324, 2325, 2326, 2327, 2328, 2329, 2330, 2331, 2332, 2333, 2334, 2335, 2336, 2337, 2338, 2339, 2340, 2341, 2342, 2343, 2344, 2345, 2346, 2347, 2348, 2349, 2350, 2351, 2352, 2353, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2361, 2362, 2363, 2364, 2365, 2366, 2367, 2368, 2369, 2370, 2371, 2372, 2373, 2374, 2375, 2376, 2377, 2378, 2379, 2380, 2381, 2382, 2383, 2384, 2385, 2386, 2387, 2388, 2389, 2390, 2391, 2392, 2393, 2394, 2395, 2396, 2397, 2398, 2399, 2400, 2401, 2402, 2403, 2404, 2405, 2406, 2407, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417, 2418, 2419, 2420, 2421, 2422, 2423, 2424, 2425, 2426, 2427, 2428, 2429, 2430, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2457, 2458, 2459, 2460, 2461, 2462, 2463, 2464, 2465, 2466, 2467, 2468, 2469, 2470, 2471, 2472, 2473, 2474, 2475, 2476, 2477, 2478, 2479, 2480, 2481, 2482, 2483, 2484, 2485, 2486, 2487, 2488, 2489, 2490, 2491, 2492, 2493, 2494, 2495, 2496, 2497, 2498, 2499, 2500, 2501, 2502, 2503, 2504, 2505, 2506, 2507, 2508, 2509, 2510, 2511, 2512, 2513, 2514, 2515, 2516, 2517, 2518, 2519, 2520, 2521, 2522, 2523, 2524, 2525, 2526, 2527, 2528, 2529, 2530, 2531, 2532, 2533, 2534, 2535, 2536, 2537, 2538, 2539, 2540, 2541, 2542, 2543, 2544, 2545, 2546, 2547, 2548, 2549, 2550, 2551, 2552, 2553, 2554, 2555, 2556, 2557, 2558, 2559, 2560, 2561, 2562, 2563, 2564, 2565, 2566, 2567, 2568, 2569, 2570, 2571, 2572, 2573, 2574, 2575, 2576, 2577, 2578, 2579, 2580, 2581, 2582, 2583, 2584, 2585, 2586, 2587, 2588, 2589, 2590, 2591, 2592, 2593, 2594, 2595, 2596, 2597, 2598, 2599, 2600, 2601, 2602, 2603, 2604, 2605, 2606, 2607, 2608, 2609, 2610, 2611, 2612, 2613, 2614, 2615, 2616, 2617, 2618, 2619, 2620, 2621, 2622, 2623, 2624, 2625, 2626, 2627, 2628, 2629, 2630, 2631, 2632, 2633, 2634, 2635, 2636, 2637, 2638, 2639, 2640, 2641, 2642, 2643, 2644, 2645, 2646, 2647, 2648, 2649, 2650, 2651, 2652, 2653, 2654, 2655, 2656, 2657, 2658, 2659, 2660, 2661, 2662, 2663, 2664, 2665, 2666, 2667, 2668, 2669, 2670, 2671, 2672, 2673, 2674, 2675, 2676, 2677, 2678, 2679, 2680, 2681, 2682, 2683, 2684, 2685, 2686, 2687, 2688, 2689, 2690, 2691, 2692, 2693, 2694, 2695, 2696, 2697, 2698, 2699, 2700, 2701, 2702, 2703, 2704, 2705, 2706, 2707, 2708, 2709, 2710, 2711, 2712, 2713, 2714, 2715, 2716, 2717, 2718, 2719, 2720, 2721, 2722, 2723, 2724, 2725, 2726, 2727, 2728, 2729, 2730, 2731, 2732, 2733, 2734, 2735, 2736, 2737, 2738, 2739, 2740, 2741, 2742, 2743, 2744, 2745, 2746, 2747, 2748, 2749, 2750, 2751, 2752, 2753, 2754, 2755, 2756, 2757, 2758, 2759, 2760, 2761, 2762, 2763, 2764, 2765, 2766, 2767, 2768, 2769, 2770, 2771, 2772, 2773, 2774, 2775, 2776, 2777, 2778, 2779, 2780, 2781, 2782, 2783, 2784, 2785, 2786, 2787, 2788, 2789, 2790, 2791, 2792, 2793, 2794, 2795, 2796, 2797, 2798, 2799, 2800, 2801, 2802, 2803, 2804, 2805, 2806, 2807, 2808, 2809, 2810, 2811, 2812, 2813, 2814, 2815, 2816, 2817, 2818, 2819, 2820, 2821, 2822, 2823, 2824, 2825, 2826, 2827, 2828, 2829, 2830, 2831, 2832, 2833, 2834, 2835, 2836, 2837, 2838, 2839, 2840, 2841, 2842, 2843, 2844, 2845, 2846, 2847, 2848, 2849, 2850, 2851, 2852, 2853, 2854, 2855, 2856, 2857, 2858, 2859, 2860, 2861, 2862, 2863, 2864, 2865, 2866, 2867, 2868, 2869, 2870, 2871, 2872, 2873, 2874, 2875, 2876, 2877, 2878, 2879, 2880, 2881, 2882, 2883, 2884, 2885, 2886, 2887, 2888, 2889, 2890, 2891, 2892, 2893, 2894, 2895, 2896, 2897, 2898, 2899, 2900, 2901, 2902, 2903, 2904, 2905, 2906, 2907, 2908, 2909, 2910, 2911, 2912, 2913, 2914, 2915, 2916, 2917, 2918, 2919, 2920, 2921, 2922, 2923, 2924, 2925, 2926, 2927, 2928, 2929, 2930, 2931, 2932, 2933, 2934, 2935, 2936, 2937, 2938, 2939, 2940, 2941, 2942, 2943, 2944, 2945, 2946, 2947, 2948, 2949, 2950, 2951, 2952, 2953, 2954, 2955, 2956, 2957, 2958, 2959, 2960, 2961, 2962, 2963, 2964, 2965, 2966, 2967, 2968, 2969, 2970, 2971, 2972, 2973, 2974, 2975, 2976, 2977, 2978, 2979, 2980, 2981, 2982, 2983, 2984, 2985, 2986, 2987, 2988, 2989, 2990, 2991, 2992, 2993, 2994, 2995, 2996, 2997, 2998, 2999, 3000, 3001, 3002, 3003, 3004, 3005, 3006, 3007, 3008, 3009, 3010, 3011, 3012, 3013, 3014, 3015, 3016, 3017, 3018, 3019, 3020, 3021, 3022, 3023, 3024, 3025, 3026, 3027, 3028, 3029, 3030, 3031, 3032, 3033, 3034, 3035, 3036, 3037, 3038, 3039, 3040, 3041, 3042, 3043, 3044, 3045, 3046, 3047, 3048, 3049, 3050, 3051, 3052, 3053, 3054, 3055, 3056, 3057, 3058, 3059, 3060, 3061, 3062, 3063, 3064, 3065, 3066, 3067, 3068, 3069, 3070, 3071, 3072, 3073, 3074, 3075, 3076, 3077, 3078, 3079, 3080, 3081, 3082, 3083, 3084, 3085, 3086, 3087, 3088, 3089, 3090, 3091, 3092, 3093, 3094, 3095, 3096, 3097, 3098, 3099, 3100, 3101, 3102, 3103, 3104, 3105, 3106, 3107, 3108, 3109, 3110, 3111, 3112, 3113, 3114, 3115, 3116, 3117, 3118, 3119, 3120, 3121, 3122, 3123, 3124, 3125, 3126, 3127, 3128, 3129, 3130, 3131, 3132, 3133, 3134, 3135, 3136, 3137, 3138, 3139, 3140, 3141, 3142, 3143, 3144, 3145, 3146, 3147, 3148, 3149, 3150, 3151, 3152, 3153, 3154, 3155, 3156, 3157, 3158, 3159, 3160, 3161, 3162, 3163, 3164, 3165, 3166, 3167, 3168, 3169, 3170, 3171, 3172, 3173, 3174, 3175, 3176, 3177, 3178, 3179, 3180, 3181, 3182, 3183, 3184, 3185, 3186, 3187, 3188, 3189, 3190, 3191, 3192, 3193, 3194, 3195, 3196, 3197, 3198, 3199, 3200, 3201, 3202, 3203, 3204, 3205, 3206, 3207, 3208, 3209, 3210, 3211, 3212, 3213, 3214, 3215, 3216, 3217, 3218, 3219, SOCIETY FOR PROMOTING CHRISTIAN KNOWLEDGE.

BRITISH BIRDS. Beautifully Illustrated in Colours. By R. BOWDLER SHARPE, LL.D., F.L.S. Crown 4to, 10s 6d

BIRDS, A Chapter on.—RARE BRITISH VISITORS. By R. BOWDLER SHARPE, LL.D., F.L.S., &c. (Zoological Department, British Museum). With 18 beautifully Coloured Plates. Crown 8vo, cloth boards, 3s 6d

"The book is teeming with interesting facts, and should be added to every bird-lover's library, as an inexpensive but thoroughly reliable work."—*Knowledge*

MATTER, ETHER AND MOTION. The Factors and Relations of Physical Science. By Professor A. B. DOLBEAR, A.B., A.M., M.E., Ph.D. With Diagrams. Crown 8vo, 5s

THIRD EDITION, REVISED AND ENLARGED
THE DAWN OF CIVILIZATION (EGYPT AND CHALDEA). By Prof. MASPERO. Edited by the Rev. Prof. SAYCE. Translated by M. L. MCCLURE. With Map and over 470 Illustrations, including 3 Coloured Plates. Demy 4to (approximately). Cloth, bevelled boards, 25s

[The Author has brought this Third Edition up to date, embodying in the volume the recent discoveries of Mr. Flinders Petrie in Egypt and some of the results of recent researches of M. Heuzey in Mesopotamia.]

THE STRUGGLE OF THE NATIONS: EGYPT, SYRIA, AND ASSYRIA. By Prof. MASPERO. Edited by the Rev. Prof. SAYCE. Translated by M. L. MCCLURE. With Maps, 3 Coloured Plates, and over 400 Illustrations. Demy 4to (approximately). Cloth, bevelled boards, 35s, half morocco (bound by Riviere), 50s

"The translation by M. L. McClure is in both cases excellent. Prof. Maspero's presentation of the new learning is at once eminently popular and attractive."—*Times*

"The author has throughout attempted to reproduce for us the daily life of the various peoples of whom he treats, and in this he has succeeded admirably."—*Academy*

HISTORICAL CHURCH ATLAS. Illustrating the History of Eastern and Western Christianity until the Reformation, and that of the Anglican Communion until the present day. By EDMUND MCCLURE, M.A. Containing 18 Coloured Maps, besides some 30 Sketch Maps in the Text. 4to, cloth boards, leather back, 16s

This Atlas is intended to indicate some of the stages of the Church's expansion, and at the same time to show briefly the interdependence of ecclesiastical and secular history. The information given on the maps has been necessarily limited by their size and number, but the main features of the spread of the Christian faith have been, it is hoped, broadly traced, and the allied changes in political geography sufficiently depicted.

"Both the readers of ancient Church history and of modern missionary records will find abundant materials in it for their avocations."—*Guardian*
"A great deal of labour and sound scholarship has gone to the making of this Atlas."—*Academy*

ANCIENT HISTORY from the MONUMENTS.—ASYRIA, from the Earliest Times to the Fall of Nineveh. By the late GEORGE SMITH, of the British Museum. New and Revised Edition by the Rev. Prof. A. H. SAYCE. Fcap. 8vo, cloth boards, 2s

ANCIENT HISTORY from the MONUMENTS.—THE HISTORY OF BABYLONIA. By the late GEORGE SMITH. Edited and brought up to date by the Rev. Prof. A. H. SAYCE. Fcap. 8vo, cloth boards, 2s

PATRIARCHAL PALESTINE. By the Rev. Prof. A. H. SAYCE, Professor of Assyriology, Oxford. Crown 8vo, with Map, buckram boards, 4s

[This book is the first to apply the Tell el Amarna Tablets, both published and unpublished, towards elucidating the condition of Syria at this period. It also contains a recent and important revision of the Egyptian Geographical Lists bearing on Palestine.]

THE "HIGHER CRITICISM" and the VERDICT of the MONUMENTS. By the Rev. Prof. A. H. SAYCE, Queens' College, Oxford. Fifth Edition. Demy 8vo, buckram, bevelled boards, 7s 6d

"A really valuable and important work, perhaps the best which Prof. Sayce has yet written."—*Academy*

THE ROMANCE OF SCIENCE.

The MACHINERY of the UNIVERSE.

Mechanical Conceptions of Physical Phenomena. By A. E. DOLEBEAR, A.B., A.M., M.E., Ph.D., Professor of Physics and Astronomy, Tufts College, Mass. Small post 8vo, with several Diagrams. Cloth boards, 2s

THE SPLASH of A DROP. By Prof. WORTHINGTON. With numerous Diagrams. Post 8vo, cloth boards, 1s 6d

OUR SECRET FRIENDS AND FOES. By PERCY FARADAY FRANKLAND, Ph.D. B.Sc. (London), F.R.S. Third Edition, Revised and Enlarged. Post 8vo, cloth boards, 3s

"It is a book which every Clergyman, every Magistrate, every Guardian of the Poor, every Governor of a School, ought to possess and master."—*Guardian*

COLOUR. By Captain Abney, F.R.S. With numerous Diagrams. Post 8vo, cloth boards, 2s 6d

COAL. By Prof. R. Meldola. With numerous Diagrams. Post 8vo, cloth boards, 2s 6d

DISEASES of PLANTS. By Prof. MARSHALL WARD. With numerous Illustrations. Post 8vo, cloth boards, 2s 6d

TIME and TIDE: a Romance of the Moon. Third Edition, Revised. By Sir ROBERT S. BAILLIE, Ph.D., F.R.S., Royal Astronomer of Ireland. Illustrated. Post 8vo, cloth boards, 2s 6d

THE STORY of a TINDER-BOX. By the late CHARLES MEYMOTT TIDY, M.B.S., F.C.S. With numerous Illustrations. Post 8vo, cloth boards, 2s

THE BIRTH and GROWTH of WORLDS. A Lecture by Prof. GREEN, M.A., F.R.S. Post 8vo, cloth boards, 1s

SOAP BUBBLES and the FORCES which MOULD THEM. Being a Course of Three Lectures delivered at the London Institution, in December 1889 and January 1890, before a Juvenile Audience. By C. V. BOYD, A.C.S.M., F.R.S. With numerous Diagrams. Post 8vo, cloth boards, 2s 6d

SPINNING TOPS. The Operatives' Lecture. A Lecture by Prof. GREEN, M.A., F.R.S. Post 8vo, cloth boards, 1s. By Prof. J. PERRY, M.E., D.Sc., F.R.S. With numerous Diagrams. Post 8vo, cloth boards, 2s 6d

THE MAKING of FLOWERS. By the Rev. Prof. GEORGE HENSLOW, M.A., F.R.S., F.G.S. With several Illustrations. Post 8vo, cloth boards, 2s 6d

THE DAWN OF EUROPEAN LITERATURE.

THE GREEK EPIC. By Prof. G. C. W. WARR, M.A. With Map. 1csp. 8vo, cloth boards, 1s. Library Edition for School Prizes, Ac. Crown 8vo, en hand made paper, top edges gilt, buckram boards, 3s, 1 calf, 7s 6d

FRENCH LITERATURE. By the late GUSTAVE MASSON, B.A., Assistant Master and Librarian of Harrow School. Fcap. 8vo, cloth boards, 2s 6d

ANGLO-SAXON LITERATURE. By the Rev. Prof. EARLE. Fcap. 8vo, cloth boards, 2s 6d

SLAVONIC LITERATURE. By W. R. MORRILL, M.A. Fcap. 8vo, cloth boards, 2s 6d
"His book will supply an admirable introduction to a systematic study of Slavonic literature."—*Scotsman*

STAR ATLAS. Gives all the Stars from 1 to 6.5 Magnitude between the North Pole and 34° South Declination, and all Nebulae and Star Clusters which are visible in telescopes of moderate power. Translated and adapted from the German of Dr. Klaproth, by the Rev. E. MCCLURE, M.A. 1csp. 4to, with 18 Charts and 80 pages Illustrative Letterpress. Cloth boards, 2s 6d

EVENINGS at the MICROSCOPE; or, Researches among the Minuter Organs and Forms of Animal Life. By the Rev. P. H. GOSSE, F.R.S. A New Edition, Revised by A. J. JEFFERY BELL, M.A., Secretary R.M.S., Professor of Comparative Anatomy and Zoology in King's College, London. Profusely Illustrated. Crown 8vo. Cloth boards, 5s

LONDON. NORTHUMBERLAND AVENUE, W.C. 43 QUEEN VICTORIA STREET, E.C. BRIGHTON. 129 NORTH STREET

MACMILLAN & CO.'S BOOKS

FOR

STUDENTS OF CHEMISTRY.

AN INTRODUCTION to the STUDY OF CHEMISTRY. By Prof. W. H. PERKIN, JR., Ph.D., F.R.S., and BEVAN LEAN, D.Sc., B.A. (Lond.). Globe 8vo, 2s. 6d.

INORGANIC CHEMISTRY for BEGINNERS. By Sir HENRY E. ROSCOE, F.R.S. Assisted by JOSEPH LUNT, B.Sc. Globe 8vo, 2s. 6d.

LESSONS in ELEMENTARY CHEMISTRY, INORGANIC and ORGANIC. By Sir H. E. ROSCOE, F.R.S. Sixth Edition, thoroughly revised. Fcap 8vo, 4s. 6d.

A TREATISE on CHEMISTRY. By Sir H. E. ROSCOE, F.R.S., and the late C. SCHORLEMMER, F.R.S. New Edition. Completely revised by Sir H. E. ROSCOE, assisted by Drs. H. G. COLMAN and A. HARDEN. Vol. I. The Non-Metallic Elements. 8vo. 21s. Vol. II. The Metals, 31s. 6d. Vol. III. Organic Chemistry. Parts I., II., IV., and VI., 21s. each. Parts III and V, 18s. each.

Material from New Britain, New Guinea, Loyalty Islands and else-
where, collected during the years 1895, 1896 and 1897. By ARTHUR
WILLEY, D.Sc. (London), Hon. M.A. (Cambridge), Balfour Student of the
University of Cambridge. Part I. Demy 8vo. With Eleven Plates
18s. 6d. (To be completed in Five or Six Parts)

CAMBRIDGE NATURAL SCIENCE MANUALS.

Biological Series. New Volumes.

General Editor, A. E. SHIPLEY, M.A., Fellow and Tutor of
Christ's College

**OUTLINES OF VERTEBRATE
PALÆONTOLOGY FOR STUDENTS OF ZOOLOGY** By A.
S. WOODWARD, M.A., Assistant Keeper of the Department of
Geology in the British Museum. Demy 8vo. 12s.

**FOSSIL PLANTS, A MANUAL FOR
STUDENTS OF BOTANY AND GEOLOGY** By A. C.
SEWARD, M.A., F.G.S., St. John's College, Lecturer in Botany in
the University of Cambridge. In 2 Vols. Vol. I. New Ready 12s.
[Vol. II. In the Press]

THE VERTEBRATE SKELETON. By
S. H. REYNOLDS, M.A., Trinity College, Cambridge, Lecturer
and Demonstrator in Geology and Zoology at University College,
Bristol. Crown 8vo. With numerous illustrations. 12s. 6d.

Geological Series.

**HANDBOOK TO THE GEOLOGY OF
CAMBRIDGESHIRE.** For the use of Students. By F. R. COWPER
REED, M.A., F.G.S., Assistant to the Woodwardian Professor of
Geology. Crown 8vo. 7s. 6d.

NATURE.—"The present work is a model of what a county geology
should be."

London C. J. CLAY & SONS,

Cambridge University Press Warehouse, Ave Maria Lane

A SCHOOL GEOGRAPHY.

By CHARLES BIRD, B.A., F.G.S.,

Headmaster of the Mathematical School, Rochester.

Crown 8vo, Cloth, 280 pp., 2s. 6d.

"This volume is distinctly in advance of the usual school books of
geography."—*Nature*

ALTERNATE CURRENTS IN PRACTICE. A Practical Treatise upon their Application to Industries
Authorized Translation from the French of LÉVY and BOUQUET by F.
J. MOFFETT, A. Inst. E.E., Electrical Engineer to the Colony of
Lagos, W. Africa. With over 60 Illustrations. Crown 8vo, 12s.

"The work gives, perhaps, the best general survey of alternate current
practice in a small compass which we have yet seen."—*Engineer*

ELECTROLYTIC METHODS OF ANALYSIS IN THEORY AND PRACTICE. Translated from
the German of Dr. HERNARD NEUMANN by J. B. C. KERSHAW,
F.R.C. With 60 Illustrations. Crown 8vo, 12s. 6d.

CONTENTS.—Theory of Electrolysis—Measuring and Regulating the
Current—The Electrolytic Procedure—Theoretical Percentage of the
Metallic Element of Certain Metallic Salts, &c.
"The second part, treating with the electrolytic separations of the
metals, is well done, and, together with the first (dealing with the de-
position of metals from pure solutions), constitutes a miniature electrolytic
Fresenius."—*Electrician*

ALTERNATING CURRENTS OF ELECTRICITY AND THE THEORY OF TRANSFORMERS
By ALFRED STILL, A.M. Inst. C.E. With 64 Illustrations. Crown
8vo, 5s.

"We can heartily commend Mr. Still's book to the class of readers for
which he has so ably written it."—*Electrical Review*

**RADIOGRAPHY AND THE X-RAYS IN
THEORY AND PRACTICE**, with Constructional and Manipu-
latory Details. By S. RUTHERFORD. With 47 Illustrations. Small
Crown 8vo, 3s.

"A quite invaluable handbook on means and methods of modern radi-
ography."—*Amateur Photographer*

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys

The Photo-Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduc-
tion of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs

The instrument is fitted with
an Aluminium Body, 6-in.
Azimuthal Circle, reading with
Vernier to one minute of arc,
4 in Compass, divided to half
degrees Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £448.

Descriptive Pamphlets and Illustrated Description
of the Instrument sent free on application.

COUNTY BOROUGH OF DERBY, MUNICIPAL TECHNICAL COLLEGE.

WANTED—(1) A Lecturer for the Subjects of Inorganic Chemistry (Practical and Theoretical), Physiology and Hygiene (2) A Lecturer for the Subjects of Pure and Applied Mathematics, including Theoretical Mechanics, Sound, Light and Heat, and Electricity and Magnetism. The Lecturers must be prepared to devote their whole time to the work. For Form of Application, and particulars of duties, send stamped addressed foolscap envelope, to the SECRETARY. Last day for Application, September 12. Duties commence on October 3.

HARTLEY COLLEGE, SOUTH-AMPTON.

Applications are invited for the Post of ASSISTANT LECTURER and DEMONSTRATOR IN PHYSICS and ELECTRICAL ENGINEERING.

A special knowledge of Experimental Physics or of Electrical Engineering, but not of both, is required. Salary, £250 per annum.

Applications must be received on or before Saturday, September 17, 1898. Particulars may be obtained on application to the CLERK.

WANTED.—CHIEF CHEMIST and MANAGER OF WORKS, by a leading London Firm of Manufacturing Chemists employing several hundred people. The qualifications necessary for the position are high and well grounded scientific knowledge and attainments, good practical experience in carrying out manufacturing processes, exceptional powers of organization and administration, tact, good judgment, capability to direct and control scientific workers engaged in the manufacture of fine medicinal chemicals and pharmaceutical products. A gentleman with University training and Degrees preferred. The position commands a liberal salary. Replies will be treated in the strictest confidence if so desired.—Address, stating age, qualifications, and experience, to "Manager," c/o Messrs. MARKBY, STEWART, & Co., 57 Coleman Street, London.

MASON UNIVERSITY COLLEGE, BIRMINGHAM.

DIPLOMA COURSES IN CIVIL, MECHANICAL, AND ELECTRICAL ENGINEERING.

PROFESSOR F. W. BURSTALL, M.A. (Canab.), A.M.I.C.E.
LECTURER ON TECHNICAL ELECTRICITY—D. K. MORRIS, Ph.D.,
A.I.E.E.
ASSISTANT LECTURER AND DEMONSTRATOR—F. H. HUMMEL

The Technical Engineering Classes include—

LECTURES on the Strength of Materials, Theory of Steam, Gas, and other Heat Engines, Hydraulics, Machine Design, Strength of Structures, Distribution of Power

DRAWING—Design of Tools, Prime Movers, Dynamoes, and other forms of Machinery

FIELD WORK—Practical Surveying in the Field throughout the Summer Term

ENGINEERING LABORATORY—Determinations of the Strength of Materials, including Compressive, Tensile, and Torsion Tests, Experimental Study of the Steam Engine and Boiler, Friction and Efficiency Tests, the Flow of Water over Weirs and through Orifices, &c.

ELECTRICAL LABORATORY—Experiments with Continuous and Alternating Current Machines, Batteries, and Electrical Instruments, including Meters

The Courses also include—

MATHEMATICS—Principal R. S. HEATH, M.A., D.Sc.

PHYSICS—Professor J. H. POYNTING, D.Sc., F.R.S.

CHEMISTRY—Professor PRACY F. FRANKLAND, B.Sc., Ph.D., F.R.S.

GEOLOGY—Professor C. LAIWOOT, LL.D., F.R.S., F.G.S.

METALLURGY—Lecturer, G. MELLAND, B.Sc., F.R.S.N.

The DIPLOMA, which carries with it the Associateship of the College, may be obtained at the end of three years' study.
The SESSION 1898-1899 commences on Tuesday, October 4. Professor BURSTALL will attend to consult with intending Students on October 3, from 10 a.m. to 1 p.m.

For DETAILED SYLLABUS, with Particulars of Fees, Scholarships, &c., apply to the SECRETARY

TECHNICAL CLASSES

THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE

The Diplôme of the College is granted in the following Departments of Engineering and other Literatures of Applied and General Sciences

CIVIL ENGINEERING	CHEMICAL ENGINEERING
MECHANICAL ENGINEERING	METALLURGY
ING.	MINING ENGINEERING
NAVAL ARCHITECTURE	AGRICULTURE
ELECTRICAL ENGINEERING	CHEMISTRY
ING.	MATHEMATICS AND
ARCHITECTURE	PHYSICS

Special Courses of Study extending over three Academic years have been arranged in each of the above Departments. Average Fee per Session, £14 14s.

Students may enrol in any of the separate Courses of Lectures, or in any of the Laboratories, provided they are qualified to take advantage of the instruction given

The Laboratories for Practical Instruction in Physics, Chemistry, Technical Chemistry, Metallurgy, and Electrical Engineering, and the Engineering Workshop, are liberally equipped with the most approved Apparatus.

Session 1898-99 commences on MONDAY, OCTOBER 3. Entrance Examination begins on TUESDAY, SEPTEMBER 27.

For Calendar (price 1s. 4d. by Post), containing detailed Syllabuses of each Course, particulars of Fees, Scholarships, &c., apply to
JOHN YOUNG, B.Sc., Secretary

DAY AND EVENING CLASSES

The Session commences SEPTEMBER 28, 1898

UNIVERSITY OF LONDON—Complete Day Courses for all the Examinations in Science, and complete Evening Courses for all the Examinations for Science, Arts, and Law Degrees

SCIENCE CLASSES in every Branch, with Practical Work. Well equipped Laboratories.

LECTURES on Political Economy and Commercial Geography. CLASSES in Languages, Commercial and English Subjects, Common Law, Bankruptcy, Equity and Conveyancing, Logic, Psychology, and Ethics.

SCHOOL OF ART (Day and Evening) Drawing, Painting, Designing, Modelling, Life Classes, &c.

CIVIL SERVICE Assistant Surveyor of Taxes, &c., Second Division, &c. Prospectus, Calendar (6d., Post free 8d.), and Syllabuses on application to the SECRETARY.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

CHAIRMAN OF THE COUNCIL, LORD LISTER, F.R.S.

The WINTER SESSION commences on Tuesday, October 4, when the New Laboratories of the Institute will be available for investigation and instruction in the following branches of work—

- 1 Bacteriology in relation to Medicine and Pathology.
- 2 Bacteriology in relation to Hygiene.
- 3 Bacteriology of Fermentation Processes.
- 4 Biological Chemistry
- 5 Photomicrography

A Practical Course, illustrating the Principles of Hygiene, will be given in the Bacteriological and Chemical Laboratories, and will include all the Laboratory Instruction necessary for the Diploma in Public Health

Facilities and help will be given to those wishing to carry out original investigations in connection with Bacteriology or Hygiene

Further particulars on application to

THE DIRECTOR.

Chelsea Bridge, S.W.

KING'S COLLEGE, LONDON.

Students in Arts and Science, Engineering, Architecture, and Applied Sciences, Medicine, and other branches of Education will be admitted for the next Term Tuesday, October 4. EVENING CLASSES commence Thursday, October 6.

Students are chosen on entrance according to their proficiency, and terminal reports of the progress and conduct of Matriculated Students are sent to their parents and guardians. There are Entrance Scholarships and Exhibitions.

Students who are desirous of studying any particular subject or subjects, without attending the complete Course of the various Faculties, can be admitted as Non-Matriculated Students on payment of the Separate Fee for such Classes in which they select.

There are a few Vacancies for Resident Students.

The College has an entrance both from the Strand and from the Thames Embankment, close to the Temple Station.

For Prospectus and all information apply to the SECRETARY, King's College London W.C.

BACTERIOLOGICAL DEPARTMENT.

KING'S COLLEGE, LONDON

Director Prof. CROOKSHANK

Demonstrator GEORGE NEWMAN, M.D., F.R.S. (Edin.).

L.P.H. (Camb.)

Assistant Demonstrator JOHN WILKINSON, M.B., D.P.H. (I and II)

The Laboratory will be re-opened on Monday, October 3. The PRACTICAL COURSE for Medical Practitioners, Veterinary Surgeons, Analysts, &c., will commence on October 5.

The Special Instruction for CANDIDATES for the DIPLOMA OF PUBLIC HEALTH will be given daily, and those wishing to join this Class are requested to send in their names as early as possible.

For particulars of the above, and of all other Classes, and of the facilities for Original Research, application should be made to the SECRETARY.

UNIVERSITY COLLEGE, BRISTOL.

CHEMICAL DEPARTMENT

Professor—SYDNEY YOUNG, D.Sc., F.R.S.

Lecturer—FRANCIS R. FRANCIS, B.Sc., Ph.D.

Demonstrator—D. H. JACKSON, M.A., B.Sc., Ph.D.

The SESSION 1898-99 begins on October 4. Lectures on Inorganic, Organic and Advanced Chemistry will be delivered during the Session. The Laboratories are fitted with the most recent improvements for the study of Practical Chemistry in all its branches. In the Evening the Laboratory is opened and Lectures on Inorganic Chemistry, at reduced fees, are delivered several Scholarships are tenable at the College.

For Prospectus and further particulars apply to JAMES RAPER, Secretary

CAI ENIDAR, containing full information, price 1s. (By Post 1s. 4d.).

For Prospectus and further particulars apply to JAMES RAPER, Secretary

VICTORIA UNIVERSITY.

THE YORKSHIRE COLLEGE, LEEDS.

The 35th Session of the Department of Science, Technology, and Arts will begin on October 11, and the 58th Session of the School of Medicine on October 3, 1901.

The Classes prepare for the following Professions: Chemistry, Civil, Mechanical, Electrical, and Sanitary Engineering, Mining, Textile Industries, Dyeing, Leather Manufacture, Agriculture, School Teaching, Medicine, and Surgery.

University Degrees are also conferred by the Faculties of Arts, Science, Medicine, and Surgery.

Lyddon Hall has been established for Students' residence.

Prospectus of any of the above may be had from the REGISTRAR.

CITY OF LONDON COLLEGE,

WHITE STREET, MOORFIELDS, E.C.

Michaelmas Term commences on September 28. Classes are held in Chemistry (Organic and Inorganic), Agriculture, Botany, Biology, Geology, &c. The Chemical and Physical Laboratories offer exceptional facilities for Practical Work.

William O. Smith

Affords a Theoretical and Practical Training, and qualifies the Sons of Gentlemen for Appointments in Mechanical and Electrical Engineering after the Preliminary Training in Theory at the Institution, Students go through a Practical Course, first in the Mechanical Engineering Works and subsequently the Electrical Works, the Institution being associated with over 30 leading Firms and Engineers for this purpose. They are thus brought directly into association with prominent Companies and Firms, and secure an introduction to the Profession under the most favourable auspices. **APPOINTMENTS HAVE BEEN SECURED FOR OVER 80 PER CENT OF THE STUDENTS** who have completed their Course since the foundation of the Institution, and applications continue to be received for competent men. Prospectus on application. The next Session commences on September 21.

UNIVERSITY OF GLASGOW. COURSES IN ENGINEERING SCIENCE

The Session opens on October 30.

NATURAL PHILOSOPHY—Prof. Lord Kelvin, D.C.L., F.R.S., M.Inst.C.E.
GEOLOGY—Prof. John Young, M.D.
CHEMISTRY—Prof. John Ferguson, M.A., LL.D.
MATHEMATICS—Prof. William Jack, M.A., LL.D.
ENGINEERING—Prof. Archibald Barr, D.Sc., M.Inst.C.E.
NAVAL ARCHITECTURE AND MARINE ENGINEERING—Prof. J. Haywood Biles, M.I.N.A.

ELECTRICAL ENGINEERING—Mr. John D. Cormack, B.Sc.

Prospectuses of the Courses, with Regulations for the Degrees of B.Sc. and D.Sc. in Engineering Science, and a List of Bursaries and Scholarships open to Science Students, can be had from the ASSISTANT CLERK.

HARTLEY COLLEGE, SOUTH-AMPTON.

SESSION 1898-99.

PRINCIPAL—R. WALLACE STEWART, D.Sc. (London)

The Day Classes of the College include the following Courses—
London University Courses in Arts and Science (Matriculation, Intermediate, and Final Courses in Arts and Science).
Science Courses for Medical Students and Dental Students.
Mechanical Engineering Courses.
Electrical Engineering Course.

NEXT SESSION COMMENCES ON SEPTEMBER 27, 1898.

Prospectuses of above Courses may be obtained on application to the CLERK.

THE ELECTRICAL GENERAL ENGINEERING COLLEGE, AND EXPERIMENTAL ENGINEERING WORKS,

2 and 4 PENYVERN ROAD, EARL'S COURT,
LONDON, S.W.

Trains Students for Electrical, Mechanical and Mining Engineering.
Develops Electrical and Mechanical Patents.
Constructs Experimental and Special Machinery and Models to Specification.

SCIENCE TUITION.

PREPARATION BY CORRESPONDENCE AND ORAL TUITION for all Science Examinations—Matriculation, B.Sc., Prel. Sci., &c. SINGLE SUBJECTS TAKEN—Chemistry, Physics, Botany, Physiology, &c. Special Classes in Botany and Chemistry.
TUTORS—The Staff includes Graduates of London, Oxford, Cambridge, and Royal Universities.

For terms and testimonials, address Mr. J. CHARLESTON, B.A., Burlington College, 27 Chancery Lane, London, W.C.

QUERNMORE. LONDON BRANCH AT 24 CHANCERY LANE, W.C.

Tuition by JOHN GIBSON, M.A. (First Class, Camb.) and G. LOY, B.A. (First Class, London), for all Public Examinations. **SPECIAL INSTRUCTION** in **Scientific Agriculture** for successful practical Agriculture and Forestry in the British Islands, Colonies, also in Geology, Botany, &c. Practical, Chemical, and Physical Laboratories. The "State Correspondent" and Higher Examination Journals given up-to-date particulars of all the leading C.S. and other Examinations. Price 2d. post free. Price of One Guinea for competition each month. Special Price of Five Guineas each June and December.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

The Winter Session, 1898-99, will commence on Monday, October 3. Dr. ARTHUR F. VOELCKERS will deliver an Introductory Address, after which the Prizes granted during the previous year will be distributed.
Two Entrance Scholarships (value £100 and £50) will be open for Competition on September 22 and 23.

One Entrance Scholarship (value £50), open to Students of the University of Cambridge who have passed the Second M.B. Exam., and of the University of Oxford who have passed the First M.B. Exam. will be competed for on September 22 and 23.
Beadle Scholarships and Prizes, there are annually Eighteen Resident Hospital Appointments open to students, without extra fee.

The Composition Fee for general Students for the whole Medical Curriculum is £20 Guinea. Special provision is made for Dental Students and for Candidates for the Preliminary Scientific (M.B.) Examination.

Special Terms are made in favour of University Students who have already commenced their Medical Studies, and of University of London Students who have passed the Preliminary Scientific Examination.

The New School Buildings, which provide new and fully equipped Laboratories for Physiology, Pathology, and Bacteriology, as well as a new Dissecting Room and Chemical Theatre and Laboratory, will be opened next Session.

The Residential College adjoins the Hospital, and provides accommodation for Third Students.
Prospectuses and all Particulars may be obtained from

W. PANTEUR, M.D., Dean

UNIVERSITY COLLEGE, LONDON.

The Session of the Faculty of Medicine will commence on October 3. Introductory Lecture, at 4 p.m., by Mr. SIDNEY SPURKS, Dental Surgeon to the Hospital.

The Examinations for the Entrance Exhibitions will commence on September 26.

Scholarships, Exhibitions, and Prizes of the value of £400 are awarded annually.

In University College Hospital about 2000 In-patients and 35,000 Out-patients are treated during the year. Thirty-six Appointments, eighteen being resident (as House Surgeon, House Physician, Obstetric Assistant, &c.), are filled up by competition during the year, and these, as well as all Clerks and Dressers, are open to Students of the Hospital without extra fee. Resident Officers receive free board and lodging.

Prospectures, with full information as to Classes, Prizes, &c., may be obtained from University College, Gower Street, W.C.

R. J. GODLEE, M.S., B.A., F.R.C.S., Dean.
J. M. HORSBURGH, M.A., Secretary.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE

PRELIMINARY SCIENTIFIC CLASS

Systematic Courses of Lectures and Laboratory Work in the subjects of the Preliminary Scientific and Intermediate B.Sc. Examinations of the University of London will commence on October 3, and continue till July, 1899.

Fee for the whole Course, £51, or £18 18s to Students of the Hospital, or single subjects may be taken.

There is a Special Class for the January Examination.
For further particulars apply to the Warden of the College, St. Bartholomew's Hospital, London, E.C.

A Handbook forwarded on application.

THE DURHAM COLLEGE OF SCIENCE, NEWCASTLE UPON-TYNE.

Principal—Rev. H. P. GURNEY, M.A., D.C.L.

The College forms part of the University of Durham, and the University Degrees in Science and Letters are open to Students of both sexes.

In addition to the Departments of Mathematics and Natural Science, complete Courses are provided in Agriculture, Engineering, Naval Architecture, Mining, Literature, History, Ancient and Modern Languages, Fine Art, &c.

Residential Hostels for men and for women. Students are attached to the College.

The Twenty-eighth Session begins September 26, 1898.

Full particulars of the University Curricula in Science and Letters will be found in the Calendar (price 2s 6d). Prospectures on application to the SECRETARY.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

ELECTRICAL ENGINEERING

Professor ANDREW GRAY, LL.D., F.R.S., will begin, in OCTOBER next, a Systematic COURSE OF INSTRUCTION in Electrical Measurement and Practical Electricity. The Physical Laboratory is fully equipped with a Compound Steam Engine, Dynamometer, Transformer, Naval Architecture, and the most approved modern Measuring Instruments for all Branches of Electrical Engineering. Laboratory Fees at the rate of £1 12 per Term for six hours per week. Composition Fee for all College Lectures for the Session, £50.

Applications for Calendar, Prospectus, and general information to be made to

J. E. LLOYD, M.A., Secretary and Registrar

CARD AND SLIP FILES.

Portion of Card File

The Ceres Card Files in Cabinets (with rod) for Literary Catalogues, and in Boxes and Trays (without the rod) for other purposes, constitute the latest development of the Card System.

The Bishop of Bristol:—"The convenience of the Writing Table with 'Ceres' Files is beyond words. So far as I can keep pace with my correspondence, there is never anxiety as to where a letter is, and the drawer with cards for notes of references, speeches, sermons, &c., makes me perpetually regret that I had not such a thing twenty years ago."

Sir H. H. Bemrose, M.P.:—"I am using the Card Box daily for a literary purpose, and I find it simply invaluable. As it lies on the table entries are made at the moment under their proper heads, and the facility of reference is such as no other mode of indexing; I am aware of can touch."

JAS. J. HICKS, 8, 9 & 10 HATTON GARDEN, LONDON.

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special
construction, and a simple and accurate arterial pressure gauge
It is marvellously sensitive, and consists of a metal tambour,
the expansion of which is exhibited in a highly magnified form
by means of an index or pointer which travels round a dial
This dial is graduated in millimetres of mercury The armet
pump and pressure gauge, when not in use, fit conveniently into
a leather case By means of this instrument we believe that
the arterial pressure can be taken in man as rapidly, simply, and
accurately as the temperature can be taken with the clinical
thermometer

Price £5 Spare Bag and Tube, 5s.

The Instrument has a 5-in Dial, and is packed in a
neat morocco Case with Handle

MACMILLAN & CO.'S NEW BOOKS

FOR

STUDENTS OF ZOOLOGY.

A TEXT-BOOK OF ZOOLOGY. By T. JEFFERY PARKER, D.Sc., F.R.S., Professor
of Biology in the University of Otago, Dunedin
of Biology in the University of Sydney, N.S.W.
In Two Vols. With Illustrations. Medium 8vo, 35s. net

LITERATURE—"The scheme of classification is on the whole so good that even those who find fault with matters of detail will admit its general excellence. The sections on Distribution—geographical, bathymetrical, and geological—and on the Philosophy of Zoology have been written with extreme care, the latter especially being full of pregnant remarks and suggestions. A useful chapter on the History of Zoology is appended, from which a true idea of the perspective of things can be gathered. Both volumes are copiously indexed, and reference to any heading is thus made easy."

A TEXT-BOOK OF ENTOMOLOGY, including the Anatomy, Physiology.
Embryology and Metamorphoses of Insects, for use in Agricultural and Technical Schools and Colleges, as well as by the
working Entomologist. By ALPHEUS S. PACKARD, M.D., Ph.D., Professor of Zoology and Geology, Brown
University. Medium 8vo, 18s. net

NATURE—"Dr. Packard's book will be of the greatest service to students of insect-anatomy, and almost indispensable to future writers on the subject. . . . should find a place in every library which includes comparative anatomy, and should be the constant companion of all who occupy themselves with the structure and life-histories of insects."

**ESSAYS ON MUSEUMS AND OTHER SUBJECTS CONNECTED WITH
NATURAL HISTORY.** By Sir WILLIAM HENRY FLOWER, K.C.B., D.C.L., D.Sc., LL.D., Ph.D., F.R.S.,
F.R.C.S., P.Z.S., Correspondent of the Institute of France, &c. Demy 8vo, 12s. net

ATHENÆUM—"Many of the essays possess permanent value, and all were well worthy of being printed afresh."

BECK'S

MICROSCOPES

* R. & J. BECK, Ltd.,
68 CORNHILL,
LONDON.

BROWNING'S PLATYSCOPIC LENS.

With Larger Angles, Increased Field, and Improved Definition

Fragment of Plate No 1
AN ACHROMATIC COMBINATION,
COMBINING THE DEFINITION OF A MICROSCOPE WITH THE
PORTABILITY OF A POCKET LENS

If you carry a small Platyscopic Pocket Lens (which every observer of
Nature ought to do) — *GRANT LIVES IN A MERE LIP*
The Platyscopic Lens is a valuable instrument to mineralogists and ento-
mologists as it is useful at three times as far from the object as the
Coddington lens. It is allowed opaque objects to be examined easily.
The Platyscopic Lens is made of four degrees of power magnifying
respectively to 15, 20 and 30 diameters — the lowest power having the largest
field in the best adapted for general use.

Price of the Platyscopic Lenses, mounted in Tortoiseshell Frames
lying either 10, 15, 20, or 30 diameters, 18s 6d each power.

DEPARTMENT OF SCIENCE AND ART. ROYAL COLLEGE OF SCIENCE FOR IRELAND.

The Session 1898-99 commences on TUESDAY, OCTOBER 4.
Diplomas of Associateship are given in the Faculties of Manufactures (Chemical), Engineering, Mining, Applied Physics (for Electrical Engineers, &c.), and Natural Science.
Two Royal Scholarships are competed for at the end of the first year, giving Free Admission to all the Courses for the two following years, and an allowance of £50 per annum.
The Courses of Chemistry, Physics, Botany, Zoology, Geology, and Mineralogy qualify for the Examinations at the Royal University (Ireland) and elsewhere. Certificates are granted to Medical, Pharmaceutical, and other Students for Special Courses.
The Chemical, Physical, Botanical, Geological, and Mineralogical Laboratories open for Practical Work.
All Classes are open to Ladies.

PROFESSORS

CHAIRMAN —
MINING AND MINERALOGY — J. P. O'REILLY, C.E., M.R.I.A.
PHYSICS — W. F. BARRETT, F.R.S.E., M.R.I.A.
CHEMISTRY — W. N. HARTLEY, F.R.S., F.C.S., F.R.S.E.
ZOOLOGY — A. C. HADDON, M.A., M.R.I.A., F.Z.
BOTANY — T. JOHNSON, D.Sc., F.L.S., M.R.I.A.
GEOLOGY — G. RENVILLE, A. J. COLE, M.R.I.A., F.G.S.
APPLIED MATHEMATICS AND MECHANICS — W. MC FADDEN ORR, M.A.
DESCRIPTIVE GEOMETRY AND ENGINEERING — JAMES LYON, M.A.
Fees for Associates from £12 to £12 per Session, according to the Faculty and Year.
Non-Associate Students, £2 per Course (except Mathematics), Laboratory Fees from £2 upwards.
The Directors of the College, giving all information — can be had on application, personally or by letter addressed to the SECRETARIES.
NOTE — The Entrance Examination for intending Associates will be held on the First Day of the Session. Subjects — Mathematics and Elementary Practical Geometry.

MASON UNIVERSITY COLLEGE, BIRMINGHAM.

DIPLOMA COURSES IN CIVIL, MECHANICAL, AND ELECTRICAL ENGINEERING.

PROFESSOR F. W. BURSTALL, M.A. (Cantab.), M.I.C.E.
LECTURER ON ELECTRICAL ENGINEERING — D. K. MORRIS, Ph.D., A.I.E.E.
ASSISTANT LECTURER AND DEMONSTRATOR — F. H. HUMPHREY.
The Technical Engineering Classes include —
LECTURES on the Strength of Materials, Theory of Steam, Gas, and other Heat Engines, Hydraulics, Machine Design, Strength of Structures, Distribution of Power.
DRAWING — Design of Tools, Prime Movers, Dynamics, and other forms of Machinery.
FIELD WORK — Practical Surveying in the Field throughout the Summer Term.
ENGINEERING LABORATORY — Determinations of the Strength of Materials, including compressive, Bending, Tensile, and Torsion Tests, Experimental Study of the Steam Engine and Boiler, Practical Efficiency Tests, the Flow of Water over Weirs and through Orifices, &c.
ELECTRICAL LABORATORY — Experiments with Continuous and Alternating Current Machines, Batteries, and Electrical Instruments, including Motors.
The Courses also include —
MATHEMATICS — Professor R. S. HEATH, M.A., D.Sc.
PHYSICS — Professor J. H. POWELL, D.Sc., F.R.S.
CHEMISTRY — Professor PERCY F. FRANKLAND, B.Sc., Ph.D., F.R.S.
GEOLOGY — Professor C. LAPHORTE, LL.D., F.R.S., F.G.S.
METALLURGY — Lecturer, G. MELLAND, B.Sc., A.R.S.M.
THE DIPLOMA, which carries with it the Associateship of the College, may be obtained at the end of three years' study.
THE SESSION 1898-1899 commences on Tuesday, October 4. Professor BURSTALL will attend to consult with intending Students on October 4, from 10 a.m. to 12 p.m.
For DETAILED SYLLABUS, with Particulars of Fees, Scholarships, &c., apply to the SECRETARY.

VICTORIA UNIVERSITY.
THE YORKSHIRE COLLEGE, LEEDS.
The 45th Session of the Department of Science, Technology, and Art will begin on October 11, and the 68th Session of the School of Medicine on October 13, 1898.
The Classes prepared for the following Professions — Chemistry, Civil, Mechanical, Electrical, Sanitary Engineering, Mining, Textile Industries, Dyeing, Leather Manufacture, Agriculture, School Teaching, Medicine, and Surgery.
University Degrees are also conferred in the Faculties of Arts, Science, Medicine, and Surgery.
Lyddon Hall has been established for Students' residence.
Prospectus of any of the above may be had from the REGISTRAR.

TECHNICAL CLASSES. THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE.

The Diploma of the College is granted in the following Departments of Engineering and other branches of Applied and General Science —
CIVIL ENGINEERING. MECHANICAL ENGINEERING. ELECTRICAL ENGINEERING. ARCHITECTURE. CHEMICAL ENGINEERING. METALLURGY. MINING ENGINEERING. AGRICULTURE. CHEMISTRY. MATHEMATICS AND PHYSICS.

Special Courses of Study extending over three Academic years have been arranged in each of the above Departments. Average Fee per Session, £14 14s.
Students may enrol in any of the separate Courses of Lectures, or in any of the Laboratories, provided they are qualified to take advantage of the instruction given.

The Laboratories for Practical Instruction in Physics, Chemistry, Technical Chemistry, Metallurgy, Electrical Engineering and Prime Movers, and the Engineering Workshop, are liberally equipped with the most approved Apparatus.

Session 1898-99 commences on MONDAY, OCTOBER 5. Entrance Examination begins on TUESDAY, SEPTEMBER 27.
For Calendar (price 12s. 6d. by Post), containing detailed Syllabuses of each Course, particulars of Fees, Scholarships, &c., apply to —

JOHN WYNN, B.Sc., Secretary.

at Bath Street, Glasgow.

MERCHANT VENTURERS' TECHNICAL COLLEGE, BRISTOL.

PRINCIPAL — Prof. J. WERTHEIMER, B.Sc., B.A.
CIVIL AND MECHANICAL ENGINEERING — Prof. J. MUNRO, A.R.S.M., M.I. Mech. E.
ELECTRICAL ENGINEERING — Prof. ARNOLD PHILIP, B.Sc., A.R.S.M.

CHEMISTRY — Prof. J. WERTHEIMER, B.Sc., B.A.
LECTURER — G. P. DARNELL SMITH, B.Sc.
MATHEMATICS — E. S. BOUTON, M.A.

In addition to the above the College Staff includes forty Assistant Lecturers, Demonstrators, and skilled Artisans. There are nine laboratories, four workshops, a dynamo room, and a large electric light installation.

COURSES IN CIVIL, MECHANICAL, ELECTRICAL, AND SANITARY ENGINEERING, AND IN PREPARATION FOR THE BUILDING TRADES.
UNIVERSITY OF LONDON — COURSE FOR MATRICULATION AND INT. AND FIN. B. Sc. AND INT. AND FIN. B. Sc.
FEE — 12s. GUINEAS A YEAR.

NORTHERN POLYTECHNIC INSTITUTE,

HOLLOWAY ROAD, N.

(Close to Holloway Station, G. N. Railway.)

J. T. DUNN, D.Sc., Principal.

SESSION begins SEPTEMBER 19, 1898.

Courses in Mathematics and Geometry.
Lecture and Laboratory Courses in Mechanics, Physics, Chemistry, Botany, Biology, Physiology, Hygiene, and Sanitary Science.
Lecture Laboratory, Drawing, and Workshop Practice in all branches of Engineering Work.

Lectures and Drawing Practice in Building Construction, and Technical and Workshop Classes in all Building Trades Subjects.
Courses in Electrical Engineering, Lecture and Laboratory, and Trade Class for Women.

Classes in English Literature, Modern Languages, Economic and Commercial Subjects.

Courses of Lecture in connection with the London Society for the Extension of University Teaching.

Classes for Civil Service Work and for London University Examinations.

Special Training Courses for Teachers.

Classes in Needlework, Dressmaking, Millinery, Domestic Economy.

School in course of erection.

Classes in Eloquence and Music, Ambulance and Nursing Courses.

Detailed Prospectus on application.

E. GRIFFITHS, Secretary.

UNIVERSITY OF GLASGOW. COURSES IN ENGINEERING SCIENCE.

The Session opens on October 20.

NATURAL PHILOSOPHY — Prof. Lord Kelvin, D.C.L., F.R.S., M. Inst. C.E., M. Inst. N.A.

GEOLOGY — Prof. John Young, M.D.

CHEMISTRY — Prof. John Ferguson, M.A., LL.D.

MATHEMATICS — Prof. William James, M.A., LL.D.

ENGINEERING — Prof. Archibald Barr, D.Sc., M. Inst. C.E.

NAVAL ARCHITECTURE AND MARINE ENGINEERING — Prof. J. Harvard Blyth, M. Inst. N.A., M. Inst. C.E.

ELECTRICAL ENGINEERING — Mr. John D. Cornack, B.Sc.

Prospectuses of the Courses, with Regulations for the Degrees of B.Sc. and D.Sc. in Engineering Science, and a List of Bursaries and Scholarships open to Science Students, can be had from the ASSISTANT CLERK.

DAY AND EVENING CLASSES

The Session commences SEPTEMBER 28, 1898

UNIVERSITY OF LONDON—Complete Day Courses for all the Examinations in Science, and complete Evening Courses for all the Examinations for Science, Arts, and Law Degrees.

SCIENCE CLASSES in every Branch, with Practical Work. Well equipped Laboratories.

LECTURES on Political Economy and Commercial Geography. CLASSES in Languages, Commercial and English Subjects, Common Law, Bankruptcy, Equity and Conveyancing, Logic, Psychology, and Ethics.

SCHOOL OF ART (Day and Evening) Drawing, Painting, Designing, Modelling, Life Classes, &c.

CIVIL SERVICE ASSOCIATION. Surveyors of Taxes, &c., Second Division, &c.

Prospectus, Calendar (6d., Post free 8d.), and syllabuses on application to the SECRETARY.

KING'S COLLEGE, LONDON.

Students in Arts and Science, Engineering, Architecture, and Applied Sciences, Medicine, and other Faculties of Education will be admitted for the next Term Tuesday, October 4. EVENING CLASSES commence Thursday, October 6.

Students are classed on entrance according to their proficiency, and terminal reports of the progress and conduct of Matriculated students are sent to their parents and guardians. There are Entrance Scholarships and Exhibitions.

Students who are desirous of studying any particular subject or subjects, without attending the complete Course of the various Faculties, can be admitted as Non-Matriculated Students on payment of the separate Fees for such Classes as they select.

There are a few Vacancies for Resident Students.

The College has an entrance both from the Strand and from the Thames Embankment, close to the Temple Station.

For Prospectus and all information apply to the SECRETARY, King's College, London W.C.

BACTERIOLOGICAL DEPARTMENT.

KING'S COLLEGE, LONDON.

Director Prof. CROOKSHANK

Demonstrator GEORGE NEWMAN, M.D., F.R.S. (Edin.),

D.P.H. (Camb.)

Assistant Demonstrator JOHN WILKINSON, M.B., D.P.H. (Lond.)

The Laboratory will be re-opened on Monday, October 3.

The Practical Course for Medical Practitioners, Veterinary Surgeons, Analysts, &c., will commence on October 5.

The Special Instruction for CANDIDATES for the DIPLOMA of PUBLIC HEALTH will be given daily, and those wishing to join this Class are requested to send in their names as early as possible.

For particulars of the above, and of all other Classes, and of the facilities for Original Research, application should be made to the SECRETARY.

BEDFORD COLLEGE, LONDON

(FOR WOMEN),

YORK PLACE, BAKER STREET, W.

Principal—Miss ETHEL HURLBATT

The Session for 1898-99 begins on Thursday, October 6. Students are expected to enter their names between 2 and 4 o'clock on Wednesday, October 5.

The Inaugural Lecture will be delivered by Professor SYLVANUS THOMPSON, D.Sc., F.R.S., at 4.30 p.m. on Thursday, October 6.

Further information on application to the PRINCIPAL.

For continuation of Advertisements relating to Colleges, Schools, &c., see page clxvi.

REISSUE OF

STANFORD'S COMPENDIUM

OF

GEOGRAPHY & TRAVEL.

ENLARGED, AND IN GREAT PART REWRITTEN

In 12 Volumes, with New Illustrations and Maps, 15s. each.

"The new issue of 'Stanford's Compendium of Geography and Travel' is a publication of great value, and contains, in convenient form, the latest geographical results of travel and research adequately treated. Not only is the information accurate, but the form in which the work is produced is admirable, and English geography may be proud of such a series. It is useful for educational purposes and for reference, and pleasant to the general reader."—*Athenium*

Just Published, large crown 8vo, cloth, 15s.

NORTH AMERICA.

VOL. II.

THE UNITED STATES.

By HENRY GANNETT,

Chief Geographer of the United States Geological Survey

With 16 Maps and 72 Illustrations

The Volumes already issued of the New Series include—

NORTH AMERICA.—Vol. I. CANADA and NEWFOUNDLAND. By SAMUEL EDWARD DAWSON, LL.D. (Lond.), F.R.S.C. With 16 Maps and 90 Illustrations.

"The general scope and execution of the work, like those of its predecessors, are admirable."—*Athenium*"The author has done his work thoroughly, giving a fuller and more satisfactory account of the Dominion than has previously been published."—*Geog. Rev.*

AUSTRALASIA.—Vol. I. AUSTRALIA and NEW ZEALAND. By ALFRED RUSSELL WALLACE, LL.D., D.C.L., F.R.S. With numerous Maps and Illustrations.

"To the general reader, and especially to the subdivision of that extensive genus included in the term 'interesting visitors' to Australia, Dr. Wallace's book may be confidently recommended."—*Sunday Review*AUSTRALASIA.—Vol. II. MALAYSIA and the PACIFIC ARCHIPELAGOES. By F. H. GUILLEMER, M.D., Author of "The Cruise of the *Albatross*." With numerous Maps and Illustrations."Dr. Guillemer's volume is certainly the most interesting and accurate account extant on the tropical portion of the Eastern Archipelago."—*Nature*

AFRICA.—Vol. I. NORTH AFRICA. By A. H. KEANE, F.R.G.S., Author of "Asia" in same Series, "Eastern Geography," &c. With 9 Maps and 77 Illustrations.

"The preparation of the book must have involved immense and original labour, for the volume in the former series by the late Keith Johnston has been entirely superseded. Mr. Keane is to be complimented on the manner in which he has discharged his task."—*Glasgow Herald*

AFRICA.—Vol. II. SOUTH AFRICA. By A. H. KEANE, F.R.G.S., Author of "North Africa" in same Series, "Eastern Geography," &c. With 11 Maps and 99 Illustrations.

"An admirable repository, not merely of geographical information proper, but of so much of history, ethnography and political vicissitudes as is required to illustrate and explain the geography."—*Times*

ASIA.—Vol. I. NORTHERN and EASTERN ASIA, CAUCASIA, RUSSIAN TURKSTAN, SIBERIA, CHINESE EMPIRE, and JAPAN. By A. H. KEANE, F.R.G.S. With 8 Maps and 67 Illustrations.

"Mr. Keane, with practical skill, has brought together a wide and most impressive array of facts and statistics, and his book has the additional advantage of numerous illustrations, a copious index, and a singularly new set of coloured maps."—*Speaker*

ASIA.—Vol. II. SOUTHERN and WESTERN ASIA, AFGHANISTAN, INDIA, INDO CHINA, MALAY PENINSULA, TURKEY IN ASIA, ARABIA, and PERSIA. By A. H. KEANE, F.R.G.S. With 7 Maps and 67 Illustrations.

"Like the first volume, it has been almost entirely recast and to a large extent rewritten. The two volumes form a most useful summary of the geography of what is in some respects the most interesting of all the continents."—*Times*

"EUROPE" and "CENTRAL AND SOUTH AMERICA" are in active preparation.

London. EDWARD STANFORD,

26 and 27 Cockspur Street, Charing Cross, S.W.

Geographer to Her Majesty the Queen.

BLAKESLEY'S WIDE-ANGLE SEXTANT

For determining Angles up to 180°
without Parallax error

Joint Patentee,
J. H. STEWARD

PRICE
£10 10s.
COMPLI TE

This is a most use-
ful Instrument for
Explorers, and for

River and Coast Surveys,
Laying out Railway
Curves, &c

TESTIMONIAL

DEAR SIR,—I have found your Blakesley Wide angle Sextant extremely
useful and reliable in taking observations during my recent trip across
Rhodesia. Yours truly (Signed) DR. HENRY G. SCHLICHTER

J. H. STEWARD,
408 STRAND, 457 WEST STRAND,
7 GRACECHURCH STREET, LONDON.

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect Instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys

The Photo-Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduction
of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation
of the photographs

The Instrument is fitted with
an Aluminium Body, 6-in
Azimuthal Circle, reading with
Vernier to one minute of arc,
4-in Compass, divided to half
degrees. Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description
of the Instrument sent free on application

WORKS—38-36 Cambridge Street, and 18-15 Crescent, BIRMINGHAM.

THE SCIENTIFIC MAN'S, NATURALIST'S, AND TRAVELLER'S CAMERA IS THE

Stereoscopic Company's BINOCULAR,

Because when ready to take 12 Pictures it weighs 19 ounces only.

It is used like a Field Glass. Takes instantaneous and time exposures. Gives Pictures 7 in by 5 1/2
when used with the simple printing and enlarging apparatus. Price £6 6s. only. Complete with enlarging
apparatus, £10 10s. FREE Lessons to Purchasers.

From R. BOWDLER SHARPE, Esq., LL.D., Assistant Keeper, Zoological Department, British Museum.

"I have received the remainder of the proofs of my photographs, and I must say that I am delighted with
them. I consider it one of the best days' work I ever did when I bought one of your 'Binocular' Camerae.
The ease with which it is worked, and the excellent results obtained, make it a most pleasurable accompani-
ment of a summer's outing, and, in my case, 90 per cent. of my Norway photographs have come out beauti-
fully, while even the small remainder cannot be considered failures. I think this is a grand result, when you
remember that I had little or no experience of photography, and had only time for an hour's instruction in
your rooms the day before I sailed, and, further, that I had to make my own dark rooms in Norway in the
best way I could. I am looking forward to having much pleasure this summer from the faithful 'Binocular,'
and I have recommended it to all my friends."

CATALOGUES ON APPLICATION

MACMILLAN & CO'S BOOKS

FOR

STUDENTS OF ZOOLOGY.

A TEXT-BOOK OF ZOOLOGY. By T. JEFFERY PARKER, D Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin N.Z., and WILLIAM A. HASWELL, M.A., D.Sc., F.R.S., Professor of Biology in the University of Sydney, N.S.W. In Two Vols. With Illustrations. Medium 8vo, 36s net.

LITERATURE—"The scheme of classification is on the whole so good that even those who find fault with matters of detail will admit its general excellence. The sections on Distribution—geographical, bathymetrical, and geological—and on The Philosophy of Zoology have been written with extreme care, the latter especially being full of pregnant remarks and suggestions. A useful chapter on the History of Zoology is appended, from which a true idea of the perspective of things can be gathered. Both volumes are copiously indexed, and reference to any heading is thus made easy."

A TEXT-BOOK OF ENTOMOLOGY, including the Anatomy, Physiology, Embryology and Metamorphoses of Insects, for use in Agricultural and Technical Schools and Colleges, as well as by the working Entomologist. By ALPHIEUS S. PACKARD, M.D., Ph.D., Professor of Zoology and Geology, Brown University. Medium 8vo, 18s net.

NATURE—"Dr. Packard's book will be of the greatest service to students of insect anatomy, and almost indispensable to future writers on the subject. It should find a place in every library which includes comparative anatomy, and should be the constant companion of all who occupy themselves with the structure and life histories of insects."

ESSAYS ON MUSEUMS AND OTHER SUBJECTS CONNECTED WITH NATURAL HISTORY. By Sir WILLIAM HENRY FLOWER, K.C.B., D.C.L., D.Sc., LL.D., Ph.D., F.R.S., F.R.C.S., P.Z.S., Correspondent of the Institute of France, &c. Demy 8vo, 12s net.

ATHENÆUM—"Many of the essays possess permanent value, and all were well worthy of being printed afresh."

A TEXT-BOOK OF COMPARATIVE

ANATOMY. By Dr. ARNOLD LANG, Professor of Zoology in the University of Zürich. With Preface to the English Translation by Dr. ERNST HAECKEL. Translated by HENRY M. BERNARD, M.A. Cantab., and MARILYN BERNARD. Vols I and II (completing the Invertebrates). 8vo. 17s net each.

LESSONS IN ELEMENTARY ANATOMY. By ST. GEORGE MIVART, F.R.S., Author of "The Genesis of Species." Fcap 8vo. 6s 6d.

ELEMENTS OF THE COMPARATIVE

ANATOMY OF VERTEBRATES. Adapted from the German of ROBERT WIEDERSHEIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Freiburg, in Baden. By W. NEWTON PARKER, Professor of Biology in the University College of South Wales and Monmouthshire. With additions by the Author and Translator. 270 Woodcuts. Medium 8vo. Second Edition. 12s. 6d net.

The STRUCTURE of MAN. An INDEX to his PAST HISTORY. By ROBERT WIEDERSHEIM. Translated by H. and M. BERNARD. The Translation, Edited and Annotated, and a Preface written by G. B. HOWES, F.R.S., Professor of Zoology, Royal College of Science, London. With 105 Figures in the Text. 8vo. 8s. net.

A COURSE OF INSTRUCTION in ZOOLOGY. Vertebrata. By T. JEFFERY PARKER, F.R.S., Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo. 8s 6d.

An INTRODUCTION to the OSTEOLOGY OF THE MAMMALIA. By Sir WILLIAM HENRY FLOWER, F.R.S., F.R.C.S., Director of the Natural History Department of the British Museum. Illustrated. Third Edition. Revised with the assistance of HANS GADOW, Ph.D., Lecturer on the Advanced Morphology of Vertebrates in the University of Cambridge. Crown 8vo. 10s 6d.

A TREATISE ON COMPARATIVE

EMBRYOLOGY. By the late Prof F. M. BALFOUR, M.A., F.R.S. In two Vols. Second Edition. Medium 8vo. Vol I 18s. Vol II 21s.

The ELEMENTS of EMBRYOLOGY.

By Prof MICHAEL FOSTER, M.D., F.R.S., and the late Prof F. M. BALFOUR, F.R.S. Second Edition, revised. Edited by A. SENGWICK, M.A., and W. HEAPE, M.A. Illustrated. Crown 8vo. 10s 6d.

STRUCTURE AND LIFE of BIRDS.

By F. W. HEADLEY, Assistant Master at Haileybury College. Illustrated. Crown 8vo. 7s 6d.

The NATURAL HISTORY of the

MARKETABLE MARINE FISHES of the BRITISH ISLANDS. By J. T. CUNNINGHAM, M.A. With Preface by E. RAY LANKESTER, F.R.S. Illustrated. Medium 8vo. 7s 6d net.

NATURAL HISTORY of AQUATIC

INSECTS. By L. C. MIALL, F.R.S., Professor of Biology in the Yorkshire College, Leeds. Illustrated. Crown 8vo. 6s.

THE ORIGIN AND METAMORPHOSES OF INSECTS. By Sir JOHN LUBBOCK, F.R.S. With Illustrations. 3s 6d. [Nature Series]

MONOGRAPH of the BRITISH

CICADÆ or TETTIGONIDÆ (Froghoppers and Grasshoppers). By GEORGE BOWDLER BUCKTON, F.R.S., Illustrated by more than 400 Coloured Drawings. Two Vols. Demy 8vo. 33s 6d each, net. Also in Eight Parts. 8s each, net.

A HANDBOOK OF BRITISH LEPIDOPTERA. By EDWARD MEYERICK, B.A., F.Z.S., F.E.S., Assistant Master at Marlborough College. Extra Crown 8vo. 10s. 6d net.

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1898-99 will open on MONDAY, October 5, when the prizes will be distributed at 3 p.m. by the Right Rev the Lord Bishop of Rochester in the Governors' Hall.
Three Entrance Scholarships will be offered for competition in September, viz.—One of £150 and one of £60 in Chemistry and Physics, with either Physiology, Botany, or Zoology, for first year's Students; one of £50 in Anatomy, Physiology, and Chemistry, for third year's Students, from the Universities.

Scholarships and money prizes of the value of £300 are awarded at the Seasonal Examinations, as well as several medals.

Special Classes are held throughout the year for the Preliminary Scientific and Intermediate M.B. Examinations of the University of London.

All Hospital Appointments are open to Students without charge.

Club Rooms and an Athletic Ground are provided for Students.

The School Buildings and the Hospital can be seen on application to the Medical Secretary.

The Fees may be paid in one sum or by instalments. Entries may be made separately to Lectures or to Hospital Practice, and Special Arrangements are made for Students entering from the Universities and for Qualified Practitioners.

A Register of approved Lodgings is kept by the Medical Secretary, who also has a List of Local Medical Practitioners, Clergymen, and others who receive Students into their households at a small fee.

For Prospectus and all particulars apply to Mr RENDLE, the Medical Secretary.

H P HAWKINS, M.A., M.D. Oxon., Dean

GUY'S HOSPITAL MEDICAL SCHOOL.

The WINTER SESSION will begin on MONDAY, OCTOBER 5. Entrance Scholarships of the combined value of £410 are awarded annually, and numerous Prizes and Medals are open for Competition by Students of the School.

The number of Patients treated in the Wards during last year exceeded 6000.

All Hospital Appointments are made strictly in accordance with the merits of the Candidates, and without extra payment. There are 58 Resident Appointments open to Students of the Hospital annually without payment of additional fees, and numerous Non-resident Appointments in the General and Special Departments. The Queen Victoria Ward, recently re-opened, will provide additional accommodation for Gynaecological and Maternity cases.

The College accommodates 60 Students, under the supervision of a Resident Warden.

The Dental School provides the full Curriculum required for the L.D.S. England.

The Club Union Athletic Ground is easily accessible.

A Handbook of Information about to enter the Medical Profession will be forwarded on application.

For the Prospectus of the School, containing full particulars as to Fees, Course of Study advised, Regulations of the College, &c., apply, personally or by letter, to the DEAN, Guy's Hospital, London Bridge, S.E.

UNIVERSITY COLLEGE, LONDON.

The Session of the Faculty of Medicine will commence on October 3. Introductory Lecture, at 4 p.m., by Mr SIDNEY SPOCKS, Dental Surgeon to the Hospital.

The Examinations for the Entrance Exhibitions will commence on September 25.

Scholarships, Exhibitions, and Prizes of the value of £600 are awarded annually.

In University College Hospital about 3000 In-patients and 35,000 Out-patients are treated during the year. Thirty-six Appointments, eighteen being resident (as House Surgeon, House Physician, Ophthalmic Assistant, &c.) are filled up by competition during the year, and these, as well as all Clerkships and Underwards, are open to Students of the Hospital without extra fee. Resident Officers receive free board and lodging.

Prospectuses, with full particulars as to Classes, Prizes, &c., may be obtained from University College, Gower Street, W.C.

R J GODFREY, M.S., B.A., F.R.C.S., Dean
J M HORSBURGH, M.A., Secretary

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.

PRELIMINARY SCIENTIFIC CLASS

Systematic Courses of Lectures and Laboratory Work in the subjects of the Preliminary Scientific and Intermediate B.Sc. Examinations of the University of London will commence on October 3, and continue till July, 1899.

Fees for the whole Course, £41, or £18 18s to Students of the Hospital, or single subjects may be taken.

There is a Special Class for the January Examination.

For further particulars apply to the Warden of the College, St. Bartholomew's Hospital, London, E.C.

A Handbook forwarded on application

VICTORIA UNIVERSITY UNIVERSITY COLLEGE, LIVERPOOL. MEDICAL FACULTY

Applications are invited for the CHAIR OF MIDWIFERY AND GYNECOLOGY, which is vacant by the death of Professor Wallace. Particulars can be procured from the Registrar, University College, Liverpool, to whom applications (with testimonials) must be sent on or before Saturday, October 8, 1898.

THE DURHAM COLLEGE OF SCIENCE, NEWCASTLE-UPON-TYNE.

Principal—Rev H. P. GURNEY, M.A., D.C.L.

The College forms part of the University of Durham, and the University Degrees in Science and Letters are open to Students of both sexes.

In addition to the Departments of Mathematics and Natural Science, courses of instruction are provided in Agriculture, Engineering, Naval Architecture, Mining, Literature, History, Ancient and Modern Languages, Fine Art, &c.

Residential Hostels for men and for women Students are attached to the College.

The Twenty-eight Session begins September 26, 1898.

Full particulars of the University Curricula in Science and Letters will be found in the Calendar (price 1s. 6d.). Prospectuses on application to the SECRETARY.

BRITISH DESIGN AND WORKMANSHIP.

Is the best All round Lens for either Professional or Amateur use
Each lens will give perfect definition with full aperture to the extreme corners of the plate
as it is sold to cover with smaller stops it will cover at least two sizes larger, giving perfect sharp
ness all over the plate and thus becoming a wide angle lens of the highest excellence. Either
combination may be used separately giving focus of about 14 and a times the length of that of
the lens when used intact. The advantage of this being able to choose the best point of view,
irrespective of distance will be at once apparent to the artistic worker

EQUIVALENT TO FOUR LENSES AT THE PRICE OF ONE

Eleven Sizes are now ready from 3 1/2 to 18 inches sq focus

MASON UNIVERSITY COLLEGE, BIRMINGHAM. **DIPLOMA COURSES IN CIVIL, MECHANICAL, AND ELECTRICAL ENGINEERING.**

PROFESSOR F. W. BURSTALL, M.A. (Cantab.), A.M.I.C.E.
LECTURER ON TECHNICAL ELECTRICITY—D. K. MORRIS, Ph.D.,
A.I.E.E.

ASSISTANT LECTURER AND DEMONSTRATOR—F. H. HUMMEL.

The Technical Engineering Classes include—

LECTURES on the Strength of Materials, Theory of Steam, Gas, and other Heat Engines, Hydraulics, Machine Design, Strength of Structures, Distribution of Power.
DRAWING—Design of Tools, Prime Movers, Dynamics, and other forms of Machinery.
FIELD WORK—Practical Surveying in the Field throughout the Summer Term.

ENGINEERING LABORATORY—Determinations of the Strength of Materials, including Compressive, Bending, Tensile, and Torsion Tests, Experimental Study of the Steam Engine and Boiler, Frictional Efficiency Tests, the Flow of Water over Weirs and through Orifices, &c.
ELECTRICAL LABORATORY—Experiments with Continuous and Alternating Current Machines, Batteries, and Electrical Instruments, including Meters.

The Courses also include—

MATHEMATICS—Principal R. S. HEATH, M.A., D.Sc.
PHYSICS—Professor H. P. YOUNG, D.Sc., F.R.S.
CHEMISTRY—Professor PERCY F. FRANKLAND, B.Sc., Ph.D., F.R.S.
GEOLOGY—Professor C. L. FAWCETT, LL.D., F.R.S., F.G.S.
METALLURGY—Professor G. MULLAND, B.Sc., A.R.S.M.

The DIPLOMA, which carries with it the Associateship of the College, may be obtained at the end of three years' study.

The 18th Session 1898-1899 commences on Tuesday, October 4. Professor BURSTALL will attend to consult with intending Students on October 3, from 10 a.m. to 2 p.m.
For DETAILED SYLLABUS, with Particulars of Fees, Scholarships, &c., apply to the SECRETARY.

Large Crown 8vo, 14s.

HANDBOOK OF PHYSIOLOGY.

BY

W. D. HALLIBURTON, M.D., F.R.S.,

Professor of Physiology, King's College, London.

WITH UPWARDS OF SIX HUNDRED ILLUSTRATIONS
(INCLUDING SOME COLOURED PLATES)

"The book, as now presented to the student, may be regarded as a thoroughly reliable exposition of the present state of physiological knowledge.—THE LANCET."

"Dr. Halliburton has re-edited the work with great care and judgment, and being now quite up to date, it ought to maintain its position as one of the most popular student's text books.—MEDICAL TIMES."

London JOHN MURRAY, Albemarle Street

THE BRIDGES-LEE PHOTO-THEODOLITE

The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys

The Photo Theodolite
automatically records
on the photograph all,
or nearly all, the data
necessary for the reduction
of the photographs,
including the Magnetic
bearings,—thus con-
siderably reducing the
time spent and the risk
of error in the interpretation of
the photographs.

The instrument is fitted with
an Aluminium Body, 6-in.
Azimuthal Circle, reading with
Vernier to one minute of arc,
4-in. Compass, divided to half
degrees. Telescope with erect
and inverting Eyepieces, rapid
Rectilinear Lens with Iris Dia-
phragm and Colour Screen, six double dark Slides in Mahogany
Case, with Stand complete, £45.

Descriptive Pamphlets and Illustrated Description
of the instrument sent free on application.

With a full Index

TIMES.—"Audubon's unpublished manuscripts are the record of a long,
a varied, and an adventurous life, passed in unremitting activity and indefatigable industry. We must say at once that for the most part they are fascinating. They are sensational, instructive, and frankly autobiographical, and they show a many-sided man in his various aspects, with the absolute unreserve of innocent egotism"

MESSRS. RIVINGTONS' LIST

**AN INTRODUCTION TO PRACTICAL
QUANTITATIVE ANALYSIS** By H. P. HIGHTON, M.A.
Assistant Master at Rugby School. With 45 Diagrams. Crown 8vo
3s 6d. [Just published]

**HANDBOOKS OF PRACTICAL
SCIENCE** In Three Books, published separately
By G. H. WYATT, B.Sc. & C.E., Science Master at Emanuel
School Wandsworth Common. Crown 8vo of each
I. Mensuration, Hydrostatics, and Heat
II. Chemical Experiments
III. Experimental Mechanics

The principle of these elementary handbooks is that a learner shall find
out for himself by experiment everything he possibly can. He is told
what to do and to some extent is also directed how to draw conclusions
from his results.

A very easy introduction to practical physics containing nothing beyond
the grasp of schoolboys who are able to work vulgar fractions and decimals
correctly. Many experiments are described at length, but the value of
the book lies chiefly in the simple questions and exercises provided for the
exercise of the student's ingenuity. — *University Correspondent*

A FIRST YEAR'S COURSE OF PRACTICAL PHYSICS. Adapted for Junior Students and Beginners.
By J. F. TRISTRAM, M.A., B.Sc., Principal and Science Master at the
Hulme Grammar School, Manchester. Crown 8vo. 12s
Contents:—Length, Area, Volume, Density, Liquids, Irregular Solids,
Bulbimetric Pressures.

This little book is written for the average student and great care has
been taken to make the subject as easy and as attractive as possible. At
the same time, by the addition of Appendices, an attempt has been made to
render it equally useful to the cleverer or older student. The course has
been arranged after much experience with large classes, and the most
desirable result of keeping the whole has together is that they can all
profit by the oral instruction, which is not assisted by its use.

**ELEMENTARY NON-METALLIC
CHEMISTRY** By S. R. TROILMAN, Science Master in the High
School Nottingham. Crown 8vo with Diagrams. 12s

It gives a clear and interesting exposition of the first principles of the
subject, based upon the lectures delivered by its author to boys & girls, for
the London Matriculation and North Kensington Examinations. —
Advertiser

An attractive little volume, carefully worked, clearly printed and plainly
illustrated. — *Edinburgh Review*

RIVINGTONS, 34 King Street, Covent Garden, London

THE WORK OF ITS KIND IN THE WORLD.

It is safe to say that there are few readers of NATURE who, long before this, would not have become possessors of the "Encyclopædia Britannica," had it not for the almost prohibitive price at which this standard work has hitherto been sold.

The "Encyclopædia Britannica" is, beyond peradventure, the most remarkable summing up and condensation of human knowledge which exists in any language, and this is particularly true of its strictly scientific side. As NATURE said during the progress of the work, "Prof. Playfair has taken the only safe method of securing articles that shall embody the fullest and lightest and most accurate knowledge, by obtaining the services of those who have proved themselves at the summit in their particular departments. In the present and to future generations, therefore, this Ninth Edition of the "Encyclopædia Britannica" must be regarded as indicating the highest tide mark of the science, literature and art of the time."

But there are not many who feel inclined to invest £37 in a single work, even though it be a work of such monumental proportions as the "Encyclopædia Britannica," and this was the former price, in the cheapest binding. Considering the outlay involved—above £500,000—the price was by no means exorbitant, but it was beyond the reach of most buyers of books. By inaugurating a novel method of selling to the public direct, without the intervention of middle men or book-dealers, and by arranging for a very large edition, *The Times*, in taking over the sale of the "Encyclopædia Britannica," is enabled to offer exactly the same work as that sold by Messrs. Black, the publishers, at less than half the former price. *The Times* reprints it as a cheap edition only in respect to price, and the radical reduction is effected solely through cheap cost of manufacture on a large scale, and its method of direct dealing with the purchaser.

But *The Times* undertaking does not stop at a reduction in price from £37 to £16. There are many to whom even £16 put out all at one time is a considerable outlay, and that this class may not be shut out from this distribution, *The Times* extends what is known as the monthly payment plan. Under this plan, at the slight advance of a shilling in the pound, the purchaser may obtain the complete work, upon the preliminary payment of a single guinea. Upon receipt of the books (the entire twenty-five volumes are delivered all at one time) he pays a second guinea, and thereafter a guinea each month.

In other words, he is able to secure the most expensive work published in the English language for the outlay of 8d per day. Meanwhile, upon the payment of a single guinea he finds the entire work in his library, and has the use and enjoyment of the volume while he is completing his payments in this comfortable way.

In this bringing this splendid possession easily within the means of all, *The Times* performs a genuine public service. No book or series of books was ever produced in just the same way as the "Encyclopædia Britannica," and never was a single work which engaged the services of so many distinguished men, which required so huge an outlay of capital, or which is so indispensable for intelligent men and women.

It is a unique characteristic of the "Encyclopædia Britannica" that while it is authoritative in the highest degree—a standard in every field—it has a little of the typical and encyclopædic atmosphere. Its articles are not mere compilations; they do not form a huge structure of facts, uncoloured and unadorned. They are the work of masters in every province, yet not

nere masters of detail, but of form and exposition as well. Many of them are indeed among the finest contributions to present-day literature. To note a single one as a type, and one that is of especial interest to readers of NATURE, the late Clerk-Macpwell's brief and brilliant treatise upon "Atoms" ("Encyclopædia Britannica," vol. II.) is among the classics of science. The development of his famous address at Bradford, it is at once a review and criticism of all the various theories which have been held regarding the ultimate structure of matter from the time of Democritus, the Greek, to the daring hypothesis of vortex rings promulgated by Helmholtz and Lord Kelvin. It is as it were the last word which science has to say regarding this baffling problem.

In the "Encyclopædia Britannica" are literally hundreds of other articles of like charm, dealing with scientific subjects—hundreds more touching every topic in which an intelligent and civilised people finds interest or concern. The "Encyclopædia Britannica" might be taken volume by volume, treatise by treatise, article by article, for the individual interest which each affords. Indeed, with a corps of contributors made up of such masters of English as Huxley and Lankester, Matthew Arnold and Swinburne, Symonds and Lang, Max Müller and Seligman, Morley and Bryce, the fact could not well be otherwise.

Because it embraces all departments of human learning, and evenly and impartially presents the best results obtainable from each, the "Encyclopædia Britannica" constitutes within itself an ideal popular library. Certainly it is the foundation, the true beginning of any extensive collection of books. Not in a thousand volumes, each chosen with no understanding of books which perhaps not a dozen men living possess, would it be possible to obtain anything like so admirable a summary of all a nineteenth century man and woman wishes to know. And any thousand books which would deal with similar mastery and with the topics included in the "Encyclopædia Britannica" would cost easily £500 or £750, while under *The Times* offer the price of the "Encyclopædia Britannica" has been brought to but £16.

Thus the only barrier which ever existed against the wide distribution of this magnificent work has been stricken down. There is no reason now why the "Encyclopædia Britannica" should not be found in every private library in Great Britain. Alike for the man of wide learning seeking the most perfect and authoritative of works of reference, or for the busy man and woman seeking a broader culture and a larger fund of information, the work in the world has such value.

The detailed statement of prices and terms will be found on the succeeding page. The attention on the binding is cloth from £17 to £18, that of the half morocco, so very desirable by reason of its elegance and extreme durability, from £15 to £16 (or 55 per cent.) that on the sumptuous full morocco, a super and one for posterity, is from £16 to £17.

On the succeeding page will also be found an illustration of the handsome revolving bookcase which has been especially designed to receive the "Encyclopædia Britannica." As the "Encyclopædia" takes up a full six cubic feet of space, many find it troublesome to afford shelf room for so extensive a work. The revolving bookcase is not only exceedingly compact, but renders each volume easily accessible from the study table or easy chair, and, flushed in quarters out, it forms an admirable addition to any library or drawing room.

THE SPECIAL BOOKCASE.

For the convenience of purchasers who have not sufficient shelf-room for the ENCYCLOPÆDIA BRITANNICA, a compact revolving bookcase has been manufactured, which will be supplied (to purchasers of the ENCYCLOPÆDIA BRITANNICA only) at a price considerably less than the usual cost of so substantial a piece of furniture. It will be sold for £9 in cash, or for three monthly payments of one guinea each.

TEMPORARY PRICES FOR THE 25 VOLUMES.

SUFFICIENT PROVISION WILL BE MADE FOR THE FILLING OF ORDERS PROMPTLY POSTED, EITHER FROM THE UNITED KINGDOM OR THE COLONIES, BUT APPLICANTS WHO HESITATE MAY FIND THAT THE OFFER HAS BEEN WITHDRAWN, OR THE PRICES INCREASED, WITHOUT FURTHER NOTICE.

CASH PAYMENT.

CLOTH BINDING, £18 [the Publishers' price was £37], AND WITH THE BOOKCASE, £19. HALF MOROCCO, £20 [the Publishers' price was £45], AND WITH THE BOOKCASE, £23. FULL MOROCCO, £27. Full gilt edges, a sumptuous binding fitted for the richest collections [the Publishers' price was £65], AND WITH THE BOOKCASE, £30.

[The Cloth binding sold for £16 is of the same quality as that sold by the publishers at £37, and is as strong as a cloth binding can be. But it can be recommended only to purchasers who feel obliged to take the ENCYCLOPÆDIA BRITANNICA in that form or not at all. The size and weight of the volumes, and the permanent value of the work, alike call for a solid Half Morocco binding; and if the price of the Full Morocco within the purchaser's means, makes a splendid addition to the equipment of a handsome house.]

NOTE.—If the Purchaser sends a cheque for the full amount at the cash price shown above, he will effect a saving of One Shilling in the Guinea, and no Order Form need be used. The Form which follows is for the use of purchasers who prefer to make monthly payments.

ALL CHEQUES SHOULD BE DRAWN TO THE ORDER OF H. H. HOOPER.

MONTHLY PAYMENTS

[ONE GUINEA to be sent with Order, nothing more to be paid until the 25 volumes have been delivered, all at one time, to the purchaser.]

CLOTH BINDING, 16 Monthly Payments of ONE GUINEA each, or with Bookcase, 19 Monthly Payments of ONE GUINEA each.

HALF MOROCCO BINDING (which we recommend), 20 Monthly Payments of ONE GUINEA each, or with the Bookcase, 23 Monthly Payments of ONE GUINEA each.

FULL MOROCCO BINDING, 27 Monthly Payments of ONE GUINEA each, or with the Bookcase, 30 Monthly Payments of ONE GUINEA each.

MONTHLY PAYMENTS—ORDER FORM

ALL CHEQUES SHOULD BE DRAWN TO THE ORDER OF H. H. HOOPER

[Date]

THE MANAGER, "THE TIMES," PRINTING HOUSE SQUARE, LONDON, E.C.

I enclose One Guinea. Please send me the ENCYCLOPÆDIA BRITANNICA (9th Edition) bound in (Cloth, price 16 guineas, 1898) *Strike out* Half Morocco, price 20 guineas, *two of* Full Morocco, price 27 guineas, *three times* as volumes, and my succeeding payments on the corresponding day of each month following. Until such payments are complete, I engage that the volumes, not being my property, shall not be disposed of by sale or otherwise. I further agree that, if owing to unforeseen circumstances, of which you shall be the judge, the volumes cannot be delivered, the return of the deposit of One Guinea to me shall cancel this agreement.

Please also send a Revolving Bookcase, for which I agree to make three further monthly payments of one Guinea each, *Strike out of Bookcase not desired*.

[Signed]

[Address]

Please address the package to

If books are to be delivered beyond London Postal district, the purchaser should send the name of the railway company or shipping agent in London to whom delivery is to be made. Beyond the London postal district carriage will be at subscriber's cost.

IF THE DESIRE BEGINS TO LEAVE THIS PAGE PRINTED, AN ORDER FORM, SIMILAR TO THAT ABOVE PRINTED, MAY BE OBTAINED UPON APPLICATION TO THE PUBLISHER OF "THE TIMES."

A TABLE OF THE PRINCIPAL CONTENTS OF THE "ENCYCLOPÆDIA BRITANNICA" AND A PAMPHLET CONTAINING SPECIMEN PAGES, COLOURED PLATES AND BRIEF EXTRACTS FROM THE WORK, WILL BE SENT, POST FREE, UPON APPLICATION TO THE PUBLISHER OF "THE TIMES."

RESIDENTS of the West-end who cannot conveniently visit THE TIMES Office, may examine, at the establishment of Messrs. Chappell & Co., 30 New Bond Street, specimen volumes of THE TIMES Reprint of the ENCYCLOPÆDIA BRITANNICA. A sample of the revolving bookcase designed for the use of subscribers to the Reprint may also be seen, and orders for the volumes and the bookcases may be given, at that address.

MACMILLAN & CO.'S BOOKS FOR STUDENTS OF CHEMISTRY.

SECOND EDITION TO BE PUBLISHED IMMEDIATELY.

A HISTORY OF CHEMISTRY FROM EARLIEST TIMES TO THE PRESENT DAY. Being also an Introduction to the Study of the Science. By **ERNST VON MEYER**, Ph.D., Professor of Chemistry in the Technical High School, Dresden. Translated, with the Author's sanction, by **GEORGE M'GOWAN**, Ph.D. Second English Edition translated from the Second German Edition, with numerous Additions and Alterations.

AN INTRODUCTION to the STUDY OF CHEMISTRY. By Prof W H PERKIN, Jr., Ph.D., F.R.S., and BEVAN LEAN, D.Sc., B.A. (Lond.) Globe 8vo, 2s. 6d.

THE DIRECTOR.

THE "ENCYCLOPÆDIA BRITANNICA" AS A WORKING LIBRARY OF SCIENCE.

At the Bristol Meeting of the British Association the other day, the President of one of the Sections referred to the fact that an eminent physicist had recently made use of an interesting phenomenon—the power which certain compounds possess of rotating a polarised ray of light when it is passed through them—an entirely new fact. In reality the phenomenon has been prominent in the teachings of chemistry for the last twenty five years.

The physicist referred to may be fairly taken as a type of those specialists in science who are so much engrossed in their own particular fields as to be ignorant even of some of the familiar facts of other branches of science quite close to their own. Then there is a very much larger class, embracing a considerable share of the reading public, who are interested in scientific affairs in a general way, but who find themselves puzzled to lay hold of such books as would give them a clear and accurate introduction to the various fields of scientific work.

For one thing there are very few thoroughly accurate and reliable scientific books which are not more or less difficult of mastery. For another thing, they are usually of an exhaustive character and consume a great deal of time and time is just what the busy man of science, and the busy man and woman of everyday affairs, lacks the most. Moreover, the mere collection of a good working library of science in itself requires a knowledge of the different sciences and their bibliography, such as very few possess.

For all such causes, the "Encyclopædia Britannica" constitutes an almost invaluable possession. Indeed, one of the criticisms which was urged against it at the time of its completion—that it gave over so much of its space to scientific subjects—one that especially commends it to people so interested in the fascinating field of research. There is probably no one who would long up the antiquity of the present day, popular interest in science has been stimulated in so many ways and by so many means, even within the last five or six years, that it is now seen how far sighted was the judgment of the editors of the "Encyclopædia Britannica" in presenting Natural Science so thoroughly in its pages.

How valuable the various scientific treatises of the "Encyclopædia Britannica" are felt to be by scientific men themselves, is sufficiently indicated by the almost endless quotations which are made from these articles. One needs them everywhere. Merely to take a single example, in reviewing a recent seasonal work upon the subject of the determination of an eminent physiologist remarked in his criticism that if the reader wished to understand clearly the worthlessness of the book in question, he had merely to turn to the succinct and accurate account of the subject to be found in the "Encyclopædia Britannica." The same thing is known upon the subject at the present time.

Of course there are a great many people who look upon an encyclopædia as more or less dry and hackneyed production. That is because the average encyclopædia is simply the work of hack writers, and one does not look for fresh, vigorous, first-hand treatment of scientific subjects in such places. But the most notable characteristic of the "Encyclopædia Britannica" is that it is not the work of hacks but of masters—masters in every field of scientific thought, and not masters of mere detail alone, but of the broad principles as well. It would be somewhat frivolous to single out separate articles as a demonstration of this, but it

will not be unfair to note a few from men of recognised primacy. No writer living or dead, could be more distinctly qualified to treat of the subject of evolution in the organic world than the late Prof. Huxley, and it is he who writes the article upon this subject for the "Encyclopædia Britannica." Again, Lord Kelvin stands confessedly first among living physicists, and it is he who writes the articles for the "Encyclopædia Britannica" upon "Heat" and "Electricity." Then there is the subject of Physiology treated by Prof. Michael Foster, the President-elect of the British Association, whose larger work on Physiology (in

point, there is no single topic of importance which is not treated by a writer who is recognised as an authority upon the subject the world over. It is not even to be wondered at that the master of all the unvarnished store of knowledge and of facts and of principles which is to be found in the "Encyclopædia Britannica," but it is certainly true that any one who gains a fair working acquaintance with each of its important treatises would be among the most widely and accurately informed of men. In other words, it is possible to gain from this single work a hitherto and thorough and comprehensive scientific education.

It may be doubted if such an education could be gained in any other way within the limits of the time available to the average man of to-day. To take only one or two examples, very few people have the time this time when the mind is at its freshest and best—to go through the five large volumes of Prof. Foster's standard "Physiology" yet practically all which the lay student and lay reader wishes to know of physiology is to be found in the same writer's terse and rapid review of the subject in the "Encyclopædia Britannica." Again, for a clear knowledge of different branches of Physics—Heat and Light and Electricity and Spectroscopy and Crystallography and Mechanics—one would have to go to a half dozen or more works to Prof. Tyndall's "Heat as a Mode of Motion," to Clerk Maxwell's treatise on "Electricity and Magnetism," to Lord Rayleigh's work on "Sound," and to others of similar period and all these require time to master; and furthermore, a considerable general knowledge to be selected with judgment. Yet all of these subjects are to be found presented in a concise yet comprehensive way in the different articles of the "Encyclopædia Britannica." There is no other place where the same amount of thoroughly accurate scientific information is to be found in like compass. And what is true of Physiology and Physics is equally true of the other branches of Natural Science of Chemistry and Biology and Botany and the rest.

There is yet another side to consider, and that is the question of economy. A complete working library of science is not merely difficult of acquisition, it involved a considerable outlay as well. Under *The Times* offer the "Encyclopædia Britannica," which is just such a library, may now be had for 15s. This is a reduction from the publishers' former price (27s.) of more than 80 per cent. The rich and handsome volumes of the "Encyclopædia Britannica," if spread out in books of ordinary size, would easily make, between two and three hundred ordinary octavo volumes, so that dividing the present price by the number, it would be seen that such volumes would cost but little more than 2s. each. In other words, this most expensive of all the works yet produced in the English language is now actually within lines of cheap literature. The cheapness is wholly as to price, however, for the work sold by *The Times* is not a cheaply made one, but is as formerly sold by Messrs. Black at 37s.

Moreover, the purchaser is not required to pay for the work all at once, but may purchase it on the simple payment plan. Upon the payment of a single guinea the complete work (the entire 25 volumes delivered) is immediately promptly put in his possession. Thereafter, he has to pay only a guinea each month until his payments are completed. This means in brief that, under *The Times* offer, he may secure this great standard work for an actual outlay of but eight guineas a year.

Certainly such an offer as this has never before been made in the history of English book selling, and it is such an offer as no one who understands the value of books may well afford to neglect.

THE SPECIAL BOOKCASE.

For the convenience of purchasers who have not sufficient shelf-room for the ENCYCLOPÆDIA BRITANNICA, compact revolving bookcases have been manufactured, which will be supplied to purchasers of the ENCYCLOPÆDIA BRITANNICA only at a price considerably less than the usual cost of so substantial a piece of furniture. It will be sold for £3 in cash, or for three monthly payments of one guinea each.

(five volumes) is the standard among English speaking people. It is with a similar authority that the late Clerk Maxwell deals with the subjects of "Atoms," "Ether," "Capillary Action," "Attraction," "Diffusion," and others, such he must be peculiarly his own. So, too, it is Professor Darwin who treats of "Hides," Sir Archibald Geikie of "Antiquities," Prof. Tyndall of "Heat," Lord Rayleigh of "Optics," Prof. Romanes of "Instinct," Prof. Lankester of "Zoology," Sir William Crookes of "Assaying," Sir Norman Lockyer of the "Sun," Prof. Schuster of "Spectroscopy," Prof. Geddes of "Morphology," Alfred Russel Wallace of "The Distribution of Plants and Animals," Prof. Jux of "Light" and "Thermodynamics," and so on.

Practically every name among the foremost living men of science in England is to be found attached to some article, some treatise in this wonderful work. And what is yet more to the

ORDERS MAY BE BOOKED AT "THE TIMES" OFFICE, PRINTING HOUSE SQUARE, OR AT THE ESTABLISHMENT OF MESSRS. CHAPPELL AND CO., 9, NEW BOND STREET. SPECIMEN VOLUMES IN THE VARIOUS STYLES OF BINDING MAY BE SEEN AT THE OFFICE OF THE PUBLISHERS, 10, NORTH QUEEN STREET. A TABLE OF THE PRINCIPAL CONTENTS OF THE "ENCYCLOPÆDIA BRITANNICA," AND A PAMPHLET CONTAINING SPECIMEN PAGES, COLOURED PLATES, AND BRIEF EXTRACTS FROM THE WORK, WILL BE SENT, POST FREE, UPON APPLICATION TO THE PUBLISHERS, "THE TIMES." FULL PARTICULARS OF THE OFFER APPEAR DAILY IN THE ADVERTISING COLUMNS OF "THE TIMES."

THE SCIENTIFIC MAN'S, NATURALIST'S, AND TRAVELLER'S CAMERA

IS THE Stereoscopic Company's BINOCULAR,

Because when ready to take 12 Pictures it weighs 19 ounces only.

It is used like a Field Glass. Takes instantaneous and time exposures. Gives Pictures 7 in by 5 in when used with the simple printing and enlarging apparatus. Price £5 5s. only. Complete with enlarging apparatus, £10 10s. FREE Lessons to Purchasers.

From R. BOWDLER SHARPE, Esq., LL.D., Assistant Keeper, Zoological Department, British Museum
17 March 4, 1898

"I have received the remainder of the proofs of my photographs, and I must say that I am delighted with them. I consider it one of the best day's work I ever did when I bought one of your 'Binocular' Camera. The ease with which it is worked, and the excellent results obtained, make it a most pleasurable accompaniment of a summer's outing, and, in my case, 90 per cent of my Norway photographs have come out beautifully, while even the small remainder cannot be considered failures. I think this is a grand result, when you remember that I had little or no experience of photography, and had only time for an hour's instruction in your rooms the day before I sailed, and, further, that I had to make my own dark rooms in Norway in the best way I could. I am looking forward to having much pleasure this summer from the faithful 'Binocular,' and I have recommended it to all my friends."

THE BRIDGES-LEE PHOTO-THEODOLITE

*The most perfect instrument
invented for Survey Work in
Mountainous Districts, and for
Military or Rapid Surveys.*

The Photo-Theodolite automatically records on the photograph all, or nearly all, the data necessary for the reduction of the photographs, including the Magnetic bearings,—thus considerably reducing the time spent and the risk of error in the interpretation of the photographs.

The instrument is fitted with an Aluminium Body, 6-in. Azimuthal Circle, reading with Vernier to one minute of arc, 4-in. Compass, divided to half degrees. Telescope with erect and inverting Eye-pieces, rapid Rectilinear Lens with Iris Diaphragm and Colour Screen, six double dark Slides in Mahogany Case, with Stand complete, £46.

Descriptive Pamphlets and Illustrated Description of the instrument sent free on application.

MACMILLAN & CO'S BOOKS

FOR

STUDENTS OF ANATOMY, PHYSIOLOGY, AND EMBRYOLOGY.

Just Published, Crown 8vo, 6s.

THE LIVING ORGANISM. An Introduction to the Problems of Biology. By ALFRED EARL, M.A., late Scholar of Christ's College, Cambridge; of the Inner Temple, Barrister-at-Law.

TEXT-BOOK OF PATHOLOGICAL ANATOMY AND PATHOGENESIS. By Prof. ERNST ZIEGLER, of Tübingen. Translated and Edited for English Students by DONALD MACALISTER, M.A., M.D., B.Sc., F.R.C.P. With Illustrations. Part I.—General. Second Edition. 12s. 6d. Part II.—Special. Sections I.—VIII. Third Edition. 17s. net. Sections IX.—XV. 17s. net.

A TEXT-BOOK OF COMPARATIVE ANATOMY. By Dr. ARNOLD LANG, Professor of Zoology in the University of Zürich. With Preface to the English Translation by Dr. ERNST HAECKEL. Translated by HENRY M. BERNARD, M.A. Cantab., and MATILDA BERNARD. Vols. I and II. (completing the Invertebrates). 8vo. 17s. net each.

LESSONS IN ELEMENTARY ANATOMY. By ST. GEORGE MIVART, F.R.S., Author of "The Genesis of Species." Fcap. 8vo. 6s. 6d.

ELEMENTS OF THE COMPARATIVE ANATOMY OF VERTEBRATES. Adapted from the German of Dr. ROBERT WIEDERSHEIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Freiburg, in Baden. By Prof. W. N. PARKER. Second Edition. 12s. 6d. net.

The STRUCTURE of MAN: An INDEX to his PAST HISTORY. By ROBERT WIEDERSHEIM. Translated by H. and M. BERNARD. The Translation, Edited and Annotated, and a Preface written by G. B. HOWES, F.R.S., Professor of Zoology, Royal College of Science, London. With 105 Figures in the Text. 8vo. 8s. net.

A COURSE OF INSTRUCTION in ZOOLOGY. Vertebrata. By T. JEFFERY PARKER, F.R.S., Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo. 8s. 6d.

An ATLAS of PRACTICAL ELEMENTARY BIOLOGY. By G. B. HOWES. With a Preface by the Right Hon. T. H. HUXLEY, F.R.S. 14s.

ELEMENTARY BIOLOGY. By T. H. HUXLEY, F.R.S., and H. N. MARTIN, F.R.S. New Edition. Revised and extended by G. B. HOWES and D. H. SCOTT. 10s. 6d.

LESSONS IN ELEMENTARY BIOLOGY. By Prof. T. JEFFERY PARKER, B.Sc., F.R.S. Illustrated. Third Edition, revised. 10s. 6d.

TEXT-BOOK OF PHYSIOLOGY. By Prof. MICHAEL FOSTER, M.D., F.R.S. With Illustrations. Fifth Edition, largely revised. In Four Parts. Part I. Blood—The Tissues of Movement, the Vascular Mechanism. 10s. 6d. Part II. The Tissues of Chemical Action, with their Respective Mechanisms—Nutrition. 10s. 6d. Part III. The Central Nervous System. 10s. 6d. Part IV. The Senses and some Special Muscular Mechanisms. The Tissues and Mechanisms of Reproduction. 10s. 6d. Appendix. By A. S. LEA. 7s. 6d.

LESSONS IN ELEMENTARY PHYSIOLOGY. By THOS. H. HUXLEY, F.R.S. Illustrated. New Edition, revised. 4s. 6d. Questions, 1s. 6d.

PHYSIOLOGY. By MICHAEL FOSTER, M.D., F.R.S. With Illustrations. Fcap. 8vo. 1s. *(Science Primers.)*

PHYSIOLOGY for BEGINNERS. By M. FOSTER, M.D., F.R.S., Professor of Physiology in the University of Cambridge, and LEWIS E. SHORE, M.A., M.D., Fellow of St. John's College, Cambridge, and Senior Demonstrator of Physiology in the University of Cambridge. Globe 8vo. 2s. 6d.

A TEXT-BOOK of the PHYSIOLOGICAL CHEMISTRY of the ANIMAL BODY, including an Account of the Chemical Changes occurring in Disease. By ARTHUR GAMGEE, M.D., F.R.S. In Two Vols. Vol. I, 18s. Vol. II, 18s.

PRACTICAL PHYSIOLOGY AND HISTOLOGY: AN ELEMENTARY COURSE. By Prof. M. FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. 7s. 6d.

ELECTRO-PHYSIOLOGY. By Prof. W. BIEDERMANN. Translated by F. A. WELBY. Vols. I and II, 17s. net each.

COMPARATIVE EMBRYOLOGY: A TREATISE ON. By F. M. BALFOUR, M.A., F.R.S. Illustrated. In Two Vols. Vol. I, 18s. Vol. II, 21s.

The ELEMENTS of EMBRYOLOGY. By Prof. M. FOSTER, M.D., F.R.S., and the late FRANCIS M. BALFOUR, F.R.S. Second Edition, revised. Edited by ADAM SEDGWICK, M.A., and WALTER HRAPE. 10s. 6d.

LESSONS IN ELEMENTARY ANATOMY. By ST. GEORGE MIVART, F.R.S. With 400 Illustrations. 6s. 6d.

A TEXT-BOOK of ZOOLOGY. By Prof. T. JEFFERY PARKER, B.Sc., F.R.S., and Prof. W. A. HASWELL. In Two Vols. 36s. net.

MACMILLAN AND CO., LIMITED, LONDON.

MACMILLAN AND CO.'S NEW BOOKS.

With Maps, Plans, Portraits, and Illustrations, 8vo, 8s. 6d. net.

THE CAMPAIGN IN TIRAH, 1897-98. An Account of the Expedition against the Orakzais and Afridis under General Sir William Lockhart, G.C.B., K.C.S.I. Based (by permission) on Letters contributed to the *Times* by Colonel H. D. HUTCHINSON, Director of Military Education in India.

MORNING POST—"Scientific, lucid, and up-to-date descriptions, which, with the aid of an excellent sectional map, a number of carefully prepared plans, and many pictorial illustrations, enable the reader to realise the difficulties our soldiers had to encounter and overcome in those few eventful months."

NEW AND CHEAPER EDITION, IN ONE VOL. Extra Crown 8vo, 10s. net.

FORTY-ONE YEARS IN INDIA. By Field-Marshal Lord Roberts, V.C. With numerous Portraits, Maps, and Plans.

WORLD—"A book which is at once intensely interesting and exciting, and at the same time supplies a vast quantity of first-hand knowledge, invaluable alike to the statesman and to the political student."

BISMARCK: some Secret Pages of his History. Being a Diary kept by Dr. MORITZ BUSCH during Twenty-five Years' Official and Private Intercourse with the great Chancellor. In Three Vols. 8vo, 30s. net.

SPECTATOR—"The scandalous, as well as the political, curiosity of Europe will be amply gratified by the publication of these volumes of secret history . . . He has drawn a most remarkable picture of a great statesman."

Demy 8vo, 12s. 6d. net.

NINE YEARS AT THE GOLD COAST. By the Rev. DENNIS KEMP, late General Superintendent Wesleyan Missions Gold Coast District. With numerous Illustrations and Maps.

GLOBE—"His book makes very good reading, and contains an abundance of useful information, from which may be gleaned much that is of value to those whose labours may differ in character from his own."

NEW BOOK BY PROFESSOR SAINTSBURY

A SHORT HISTORY OF ENGLISH LITERATURE. By GEORGE SAINTSBURY, Professor of English Literature in the University of Edinburgh. Crown 8vo, 8s. 6d.

NOW READY, SECOND EDITION, WITH NUMEROUS ADDITIONS AND ALTERATIONS

A HISTORY OF CHEMISTRY FROM EARLIEST TIMES TO THE PRESENT DAY.

Being also an Introduction to the Study of the Science.

By ERNST VON MEYER, Ph.D., Professor of Chemistry in the Technical High School, Dresden. Translated, with the Author's sanction, by GORGE M'GOWAN, Ph.D.
Second English Edition translated from the Second German Edition, with numerous Additions and Alterations. 8vo, 15s. net.

NEW EDITION OF VOLUME II NOW READY.

A TREATISE OF CHEMISTRY. By H. E. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S. New Edition Completely Revised by Sir H. E. ROSCOE. Assisted by DR. H. G. COLEMAN and A. HARDEN.
Volume I.—THE NON-METALLIC ELEMENTS. 8vo, 21s. Volume II.—THE METALS. 8vo, 31s. 6d.

. It is believed that the two volumes as they now stand form not only the best but the only complete work, up to date, on **INORGANIC CHEMISTRY** in the English Language.

NATURE—"It may at once be said that the revision has been accomplished with great care, with full knowledge, and, speaking generally, with a great measure of success. . . The whole of such a volume as this should be read attentively by every serious student of chemistry; and if this treatise does not displace all other English text-books devoted to mere description, it will be solely on account of the unfortunate but unavoidable high price."

Globe 8vo, 6s.

AN INTRODUCTION TO THE SCIENCE AND PRACTICE OF QUANTITATIVE CHEMICAL ANALYSIS INORGANIC By CHAPMAN JONES, F.I.C., F.C.S. (London and Berlin), &c.

Globe 8vo, 2s. 6d.

GEOLOGY FOR BEGINNERS. By W. W. WATTS, M.A., F.G.S., formerly Lecturer to the Cambridge University Extension, and Member of Her Majesty's Geological Survey, and now Assistant-Professor of Geology at the Mason University College, Birmingham. With 310 Illustrations.

GUARDIAN—"Since geology has begun to take its place in school curricula, a work has been needed adapted to junior classes, and one which lends itself to 'getting up' for examinations. The book before us seems well designed to supply this need. . . Abundant illustrations and a copious index add to the value of a book which is evidently the work of one who knows the ground."

Demy 8vo, 14s. net.

INFINITESIMAL ANALYSIS. By WILLIAM BENJAMIN SMITH, Professor of Mathematics in Tulane University. Vol. I. Elementary Real Variables.

Globe 8vo 8s. 6d. net.

KEY TO ALGEBRA FOR BEGINNERS. By the late I. TODHUNTER, D.Sc., and S. L. LONEY, M.A.

NEW VOLUME BY MRS. BERNARD BOSANQUET.

THE STANDARD OF LIFE AND OTHER STUDIES. By Mrs. BERNARD BOSANQUET, Author of "Rich and Poor." Crown 8vo, 3s. 6d.

MACMILLAN AND CO., LIMITED, LONDON.

THE NEW STIGMATIC LENS.

SERIES II. 2/0.

BRITISH DESIGN AND WORKMANSHIP.

Is the best All-round Lens for either Professional or Amateur use. Each lens will give perfect definition with full aperture to the extreme corners of the plate it is sold to cover; with smaller stops it will cover at least two sizes larger, giving perfect sharpness all over the plate, and thus becoming a wide-angle lens of the highest excellence. Either combination may be used separately, giving field of about 1 1/2 and a times the length of that of the lens when used intact. The advantage of thus being able to choose the best point of view, irrespective of distance, will be at once apparent to the artistic worker.

EQUIVALENT TO FOUR LENSES AT THE PRICE OF ONE.

Eleven Sizes are now ready from 3 1/2 to 18 inches eq. f. 109.

THE GREATEST LANTERN NOVELTY IN THE MARKET

AERIAL GRAPHOSCOPE (BRUCE'S PATENT),

Showing Lantern Pictures in SPACE and BOLD RELIEF without
a Screen, and weird Ghost Effects and Fairy Like Visions

Exhibited with enormous success at the Salons of the Royal Society the
Royal Institution Royal Photographic Society of Arts British
Association Crystal Palace Birmingham and Midland Institute, &c.
Supplied to Owens College Manchester Queen's Theatre Manchester
Hermann's Magic Entertainment New York &c.

The Apparatus can be purchased outright or let out on hire. Exhibit one
can also be arranged at all kinds of Entertainments Soirees Photographic
Exhibitions &c. with experienced Operators

The Inventor Mr ERIC STEWART BRUCE, M.A. OXON. F.R.Met Soc.
is also prepared to accept Engagements for his Illustrated Lecture on the
subject

The Instrument forms the most perfect method of illustrating the
phenomena of Persistence of Vision to large audiences, introducing effects
which are not visible in other instruments such as the difference in identity
between real and incidental images the gradual fading of incidental images
the curious multiplication phenomena &c.

THIRD EDITION Revised and in part Re-written With Illustrations and Coloured Frontispiece

PRACTICAL GEOLOGY (Aids in). With

A Section on Paleontology. By GRENVILLE A. J. COLE, M.R.I.A. F.G.S. Professor of Geology in the Royal College of Science for Ireland.

GENERAL CONTENTS.—Sampling of the Earth's Crust—Examination of Minerals—Examination of Rocks—Examination of Fossils.

Prof. Cole treats of the examination of minerals and rocks in a way that has never been attempted before. OBSERVING OF THE HIGHEST PRAISE Here indeed are Aids INNUMERABLE and INVALUABLE. All the directions are given with the utmost clearness and precision.—*Athenaeum*. That the work deserves its title that it is full of Aids, and in the highest degree PRACTICAL, will be the verdict of all who use it.—*Nature*.

NO TEMPERATURE ERROR.

DINKES' PATENT PRESSURE PORTABLE ANEMOMETER.

For many years the want has been felt of a PORTABLE ANEMOMETER, by means of which the actual Velocity and Pressure of the Wind could be quickly ascertained. This want Mr W DINKES, who is well known for his anemometrical experiments, has met by his PATENT PRESSURE PORTABLE ANEMOMETER.

One scale of the instrument shows *directly* the actual velocity of the wind, the other (not shown in the woodcut) the pressure exerted in pounds per square foot. The instrument is used vertically, with the nozzle pointing towards the wind.

MACMILLAN AND CO'S NEW BOOKS.

NEW BOOK BY BENJAMIN KIDD

THE CONTROL OF THE TROPICS By BENJAMIN KIDD, Author of *Social Evolution* Crown 8vo 3s net

NOW READY, SECOND EDITION, WITH NUMEROUS ADDITIONS AND ALTERATIONS

A HISTORY OF CHEMISTRY FROM EARLIEST TIMES TO THE PRESENT DAY.

Being also an Introduction to the Study of the Science

By ERNST VON MEYER Ph D Professor of Chemistry in the Technical High School Dresden Translated with the Author's sanction by GEORGE M GOWAN Ph D

Second English Edition translated from the Second German Edition with numerous Additions and Alterations 8vo 15s net
SPEAKER— A standard book on the subject. In the main the conclusions of Professor von Meyer are hardly likely to be disputed for they are obviously the outcome of wide knowledge independent research and sound judgment. Dr M Gowan has rendered the original text of the book into excellent English and the marks of more than ordinary care prevail on almost every page

JAS. J. HICKS, 8, 9 & 10 HATTON GARDEN, LONDON,

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctrs HILL and BARNARD which is of special construction, and a simple and accurate arterial pressure gauge. It is marvellously sensitive and consists of a metal tambour, the expansion of which is exhibited in a highly magnified form by means of an index or pointer which travels round a dial. This dial is graduated in millimetres of mercury. The armlet pump and pressure gauge, when not in use, fit conveniently into a leather case. By means of this instrument we believe that the arterial pressure can be taken in man as rapidly simply and accurately as the temperature can be taken with the clinical thermometer.

Price £5 Spare Bag and Tube, 5s.

The Instrument has a 5-in Dial, and is packed in a neat morocco Case with Handle FULLER PARTICULARS ON APPLICATION

148, HIGH HOLBORN, LONDON, W.C.

DINES' PATENT PRESSURE PORTABLE ANEMOMETER.

For many years the want has been felt of a PORTABLE ANEMOMETER, by means of which the actual Velocity and Pressure of the Wind could be quickly ascertained. This want Mr W DINES, who is well known for his anemometrical experiments, has met by his PATENT PRESSURE PORTABLE ANEMOMETER.

One scale of the instrument shows *directly* the actual velocity of the wind, the other (not shown in the woodcut) the pressure exerted in pounds per square foot. The instrument is used vertically, with the nozzle pointing towards the wind.

THE SCIENTIFIC MAN'S, NATURALIST'S, AND TRAVELLER'S CAMERA

IS THE
Stereoscopic Company's BINOCULAR,

Because when ready to take a Picture it weighs 12 ounces only.

It is used like a field glass. Takes instantaneous and time exposures. Gives Pictures 2½ in by 1½ in when used with the simple printing and enlarging apparatus. Price £5 5s. only. Complete with enlarging apparatus. £10 10s. FREE Lessons to Purchasers

From R. BOWDLER SHARPE, Esq., LL.D., Assistant Keeper, Zoological Department, British Museum

"I have received the remainder of the proofs of my photographs, and I must say that I am delighted with them. I consider it one of the best day's work I ever did when I bought one of your 'Binocular' Cameras. The ease with which it is worked, and the excellent results obtained, make it a most pleasurable accompaniment of a summer outing, and, in my case, 90 per cent. of my Norway photographs have come out beautiful, while even the small remainder cannot be considered failures. I think this is a grand result, when you remember that I had little or no experience of photography, and had only time for an hour's instruction in your rooms the day before I sailed, and, further, that I had to make my own dark rooms in Norway in the best way I could. I am looking forward to having much pleasure this summer from the faithful 'Binocular,' and I have recommended it to all my friends."

THE NEW STIGMATIC LENS.

SERIES II 7/6

BRITISH DESIGN AND WORKMANSHIP.

Is the best All-round Lens for either Professional or Amateur use

Each lens will give perfect definition with full aperture to the extreme corners of the plate it is sold to cover. With smaller stops it will cover at least two sizes larger, giving perfect sharpness all over the plate, and thus becoming a wide angle lens of the highest excellence. Either combination may be used separately, giving foci of about 15 and 2 times the length of that of the lens when used intact. The advantage of thus being able to choose the best point of view, irrespective of distance, will be at once apparent to the artistic worker.

EQUIVALENT TO FOUR LENSES AT THE PRICE OF ONE.

Eleven Sizes are now ready from 3/2 to 18 inches eq. focus.

CATALOGUE OF HIGH-CLASS CAMERAS AND LENSES, POST FREE.

ELECTRICAL ENGINEERING.

THE ELECTRICAL STANDARDIZING, TESTING AND TRAINING INSTITUTION 8 CHARING CROSS ROAD LONDON
(Proprietors—Syndicate of Electrical Engineers Ltd.)

BOARD OF CONTROL

The Rt. Hon. the Earl of CRAWFORD, K.T., F.R.S., Chairman
The Rt. Hon. Lord Castletown, Hugh Ewart Harrison
The Hon. R. Brougham, Francis Ince
Robert Hammond, William O. Smith

Affords a Theoretical and Practical Training, and qualifies the Sons of Gentlemen for Appointments in Mechanical and Electrical Engineering. After the Preliminary Training in Theory at the Institution Students go through a Practical Course, first in the Mechanical Engineering Works and subsequently the Electrical Works, the Institution being associated with over 50 leading Firms and Engineers for this purpose. They are thus brought directly into association with prominent Companies and Firms, and secure an Introduction to the Profession under the most favourable auspices. APPOINTMENTS HAVE BEEN SECURED FOR OVER 100 P.P.R. CLERK OF THE STUDENTS who have completed their Course since the foundation of the Institute, and applications continue to be received for competent men. Prospectus on application. The new Session has just commenced.

**THE ELECTRICAL
AND
GENERAL ENGINEERING COLLEGE,
AND
EXPERIMENTAL ENGINEERING
WORKS,**

2 and 4 PENYFREN ROAD EARL'S COURT,
LONDON, S.W.

Trains Students for Electrical, Mechanical and Mining Engineering Develops Electrical and Mechanical Talents. Constructs Experimental and Special Machinery and Models to Specification.

MATRICATION B.A. & B.Sc.

PREPARATION BY CORRESPONDENCE AND ORAL TUITION on a THOROUGHLY INDIVIDUAL SYSTEM. Fees based on success if desired.

THE STAFF includes Graduates of Oxford, Cambridge, London, and Royal Universities.

SINGLY SUBJECTS TAKEN: Latin, Greek, French, German, Italian, English, Mathematics, Sciences, Logic, Psychology, Political Economy, &c.

For Terms, Testimonials from successful Pupils, & addresses Mr. J. CHARLTON, B.A. (London and Oxon), The Harrington Clauses, 27 Chancery Lane, London, W.C.

QUERNMORE, 24 CHANCERY LANE, W.C.

Tuition by JOHN GIBSON, M.A. (First Class Camb.) and G. LOYD B.A. (First Class London), for all Public Examinations. Special Instruction in Botanical Agriculture for successful practical Agriculture and Forestry in the British Islands or the Colonies, also in Geology, Botany, &c. Practical Chemical and Physical Laboratories. The State Correspondent, and Higher Examination Journal, &c. up to date particulars of all the latest &c. and other Examinations. Price paid post free. Prize of One Guinea for competition each month. Special Prize of Five Guineas each year, and December.

UNIVERSITY OF CAMBRIDGE.

THE JOHN LUCAS WALKER STUDENTSHIP

Applications for this Studentship, the holder of which shall devote his self (or herself) to Original Research in Pathology, are invited and should be sent not later than January 18, 1899, to Prof. A. RANFACK, Pathological Laboratory, Cambridge, to whom also applications for further information regarding the Studentship may be addressed.

The Studentship, which is of the annual value of at least £200, may be held by a person of either sex and is tenable under certain conditions for three years.

CHEMISTRY, PHYSICS, AND BIOLOGY.

Coaching for all Examinations. Conjoint Board, Durham, Dublin, Cambridge, Army, University of London, &c. Theoretical and Practical. Small Classes or Private Tuition. Well equipped Laboratories. Practical Forensic Medicine.—T. C., 9 Heathcote Street, Gray's Inn Road, W.C.

PHYSICS TEACHER WANTED AT

CAMBRIDGE—Preferably one with First Class Honours at London B.Sc. Elementary Mathematics desirable. Apply Physics, Office of this Paper.

RESEARCH, CHEMISTRY, & PHYSICS.

Well-fitted Laboratories can be used for Research at any hours convenient to Workers. Workshop for making Apparatus. Electric Mains for Experiments.—T. C., 9 Heathcote Street, Gray's Inn Road, W.C.

FOR SALE—Post Office Bridge, D'Arsonval

1" galvanometer, Transparent Scale and Lamp. Meter Bridge, Wall Pattern 1" galvanometer. Also Short 1" Galvanometer. Subdivided One Ohm Coil and small Key. By Electric Maker. Good as new.—Apply CANTAR, Office of this Paper.

METEORITES.

THE GREATEST LANTERN NOVELTY IN THE MARKET

**AERIAL GRAPHSCOPE
(BRUCE'S PATENT),**

Showing Lantern Pictures in SPACE and BOLD RELIEF without a Screen, and weird Ghost Effects and Fairy Like Visions

Exhibited with enormous success at the Sorétes of the Royal Society, the Royal Institution, Royal Photographic Society, Society of Arts, British Assoc. and Crystal Palace, Birmingham and Midland Institute, &c. Supplied to Owens College, Manchester, Queen's Theatre, Manchester, Her Majesty's Theatre, London, &c. The Apparatus is a portable and light and set out on hire. Exhibitions can also be given at all kinds of Entertainments. Sorétes Photographic Exhibitions &c. with expert Slide Operators. The Inventor, Mr. ERIC SYDNEY BRUCE, M.A. OXON, F.R.S. Met Soc. is also prepared to accept engagements for his Illustrated Lecture on the subject.

The Instrument forms the most perfect method of illustrating the phenomena of Perspective of Vision to large audiences, introducing effects which are not visible in other instruments, such as the difference in intensity between real and incidental images, the gradual fading of incidental images, the curious multiplication phenomena, &c.

For Prospectus and unanimous complimentary criticisms of the entire London Press apply to

NO TEMPERATURE ERROR.

DINES' PATENT PRESSURE PORTABLE ANEMOMETER.

For many years the want has been felt of a PORTABLE ANEMOMETER, by means of which the actual Velocity and Pressure of the Wind could be quickly ascertained. This want Mr W DINES, who is well known for his anemometrical experiments, has met by his PATENT PRESSURE PORTABLE ANEMOMETER.

One scale of the Instrument shows *directly* the actual velocity of the wind; the other (not shown in the woodcut) the pressure exerted in pounds per square foot. The instrument is used vertically, with the nozzle pointing towards the wind.

NEWMAN & GUARDIA, Ltd.,
90 & 92 Shaftesbury Avenue, London, W

JAS. J. HICKS,

8, 9 & 10 HATTON GARDEN, LONDON,

IS SOLE MAKER OF

THE NEW PATENT SPHYGMOMETER

Invented by Doctors HILL and BARNARD, which is of special construction, and a simple and accurate arterial pressure gauge. It is marvellously sensitive, and consists of a metal tambour, the expansion of which is exhibited in a highly magnified form by means of an index or pointer which travels round a dial. This dial is graduated in millimetres of mercury. The armlet pump and pressure gauge, when not in use, fit conveniently into a leather case. By means of this instrument we believe that the arterial pressure can be taken in man as rapidly, simply, and accurately as the temperature can be taken with the clinical thermometer.

Price £5. Spare Bag and Tube, 6s.

The Instrument has a 6-in. Dial, and is packed in a neat morocco Case with Handle.
